SUMMARY

Regulatory T (Treg) and T helper 17 (Th17) cells were recently proposed to be reciprocally regulated during differentiation. To understand the underlying mechanisms, we utilized a Th17 reporter mouse with a red fluorescent protein (RFP) sequence inserted into the interleukin-17F (IL-17F) gene. Using IL-17F-RFP together with a Foxp3 reporter, we found that the development of Th17 and Foxp3+ Treg cells was associated in immune responses. Although TGF-β receptor I signaling was required for both Foxp3 and IL-17 induction, SMAD4 was only involved in Foxp3 upregulation. Foxp3 inhibited Th17 differentiation by antagonizing the function of the transcription factors RORγt and RORα. In contrast, IL-6 overcame this suppressive effect of Foxp3 and, together with IL-1, induced genetic reprogramming in Foxp3+ Treg cells. STAT3 regulated Foxp3 downregulation, whereas STAT3, RORγt, and RORα were required for IL-17 expression in Treg cells. Our data demonstrate molecular antagonism and plasticity of Treg and Th17 cell programs.

INTRODUCTION

Naive CD4+ helper T (Th) cells, upon encountering their cognate antigens presented on professional antigen-presenting cells (APCs), differentiate into effector cells that are characterized by their cytokine production profiles and immune-regulatory functions. In addition to Th1 and Th2 cells (Dong and Flavell, 2000), a third subset of effector Th cells, Th17, has been identified; these produce IL-17, IL-17F, and IL-22 and regulate inflammatory responses by tissue cells (Dong, 2008). Th17 cell differentiation in mouse is initiated by TGF-β and IL-6. Recently, IL-21 was reported as an autocrine factor induced by IL-6 to regulate Th17 cell differentiation. STAT3, downstream of IL-6 and IL-21, is essential for RORγt and RORα expression and Th17 cell differentiation (Laurence et al., 2007; Yang et al., 2007). STAT3 may function by regulating the expression of two orphan nuclear receptors, RORγt and RORα, in developing Th17 cells (Ivanov et al., 2006; Yang et al., 2008b).

Thymus-derived natural regulatory T (nTreg) cells represent a unique subpopulation of CD4+ T cells that inhibit T cell proliferation and autoimmune responses (Wing et al., 2006). The hallmark of nTreg cells is the expression of Foxp3 transcription factor, which is required for maintaining Treg cell function (Williams and Rudensky, 2007). TGF-β has been shown to maintain peripheral nTreg cells; its deficiency leads to development of early lethal autoimmunity (Marie et al., 2005; Shull et al., 1992). Moreover, in the presence of TGF-β, Foxp3 can be also induced in naive T cells in the periphery, and the resulting inducible Treg (iTreg) cells exhibit a suppressive phenotype similar to that in nTreg cells (Wing et al., 2006).

As describe above, TGF-β is required for regulation of nTreg and iTreg cells, and it is also involved in Th17 cell differentiation. Thus, there is not only functional antagonism between Th17 and Treg cells in autoimmunity, but also reciprocal regulation in the generation of these cells. Although TGF-β induces Foxp3 expression, IL-6 and IL-21 inhibit this regulation and together with TGF-β drive Th17 cell differentiation. The molecular mechanisms underlying this differential T cell fate decision initiated by cytokines is unclear. In the present study, we have analyzed the molecular interaction of Treg and Th17 cell genetic programs in response to cytokine regulation. To better address this question, we utilized a Th17 reporter mouse with a red fluorescent protein (RFP) coding sequence inserted into the IL-17F gene. Our data reveal intrinsic association of Th17 and Treg cell genetic programs and indicated the plasticity of T cell differentiation programs.

RESULTS

Generation and Characterization of an IL-17F-RFP Reporter Mouse

To better characterize Th17 cell differentiation, we generated an IL-17F reporter strain by insertion of a cassette containing an internal ribosome entry site (IRES)-driven red fluorescent protein
(RFP) and a bovine growth hormone polyA tail into the 2nd exon of the IL-17F gene through homologous recombination in murine embryonic stem cells (Yang et al., 2008a). Heterozygous IL-17F–RFP (hereafter referred as Il17ffrfp) mice were first tested for the fidelity of RFP expression in reporting Th17 cells. Naive CD4+CD25−CD62L−CD44hi T cells were isolated from Il17ffrfp mice by fluorescence-activated cell sorting (FACS) and differentiated under Th1, Th2, Th17, and iTreg conditions. Four days after activation, RFP was highly expressed in Th17 cells but not in Th1 and Th2 cells (Figure 1A). Notably, under iTreg condition, weak expression of RFP was also observed (Figure 1A), although IL-17 protein was not expressed (data not shown).

Because not all cells differentiated under Th17 cell conditions express RFP, we next sorted RFP+ and RFP− subsets from the above Th17 culture by flow cytometry and then evaluated IL-17 and IL-17F expression by intracellular staining. In RFP+ population, there was a substantial IL-17- and IL-17F double-producing subset and an IL-17F single expression subset (Figure 1B). In contrast, RFP− cells did not express IL-17 or IL-17F. Next, we also assessed the gene expression profiles of RFP+ and RFP− cells in Th17 culture by real-time RT-PCR and compared them to Th0 (T cells differentiated under neutral conditions), Th1, Th2, and iTreg cells. The RFP+ but not RFP− population highly expressed Th17 signature genes, including Il17a, Il17f, Il22, Il21, Il23r, and Rorc (encoding RORγt), and upregulated Rora (encoding RORα) gene expression (Figure S1A available online). Th1-, Th2-, and iTreg-specific genes (Tbx21, Gata3, and Foxp3, respectively) were not highly expressed in the RFP+ cells (Figure S1A).

Because IL-17F-RFP marks Th17 cells, we further utilized T cells from Il17frfp mice to characterize the cytokine regulation of Th17 cell differentiation. Naive T cells isolated from Il17frfp mice were activated in the presence or absence of IL-6, IL-21, or TGF-β or a combination of the cytokines. Unlike the neutral condition, IL-6 or TGF-β slightly increased the number of RFP-expressing cells (Figure 1C); in these cells, IL-17F was expressed at low amounts (Figure S1B). The combination of TGF-β with IL-6 or IL-21 greatly increased the frequency of RFP-expressing cells (Figure 1C). Cytokine staining revealed that IL-17F expression correlated well with RFP expression (Figure S1B). IL-17 expression also correlated with RFP expression under IL-6, TGF-β and IL-6, or TGF-β and IL-21 conditions but not under TGF-β stimulation (Figure S1B).

Lamina propria was previously shown as a site where some T cells constitutively express IL-17 (Ivanov et al., 2006). We thus isolated lamina propria cells from wild-type, Il17ffrfp, and Il17frfp mice and examined RFP expression in CD4+ T cells. Although T cells from wild-type mice had no background fluorescence, approximately 2% from Il17ffrfp and 8% of those from Il17frfp mice expressed RFP (Figure S2A). To further characterize the RFP+ cells in lamina propria, we sorted RFP+ and RFP− fractions by flow cytometry and performed gene expression analysis by real-time RT-PCR. The RFP+ population exhibited a Th17 gene expression profile—they highly expressed IL-17, IL-17F, and IL-22 as well as upregulated IL-23R, RORα, and RORγt expression (Figure S2B).

We also utilized the reporter mice to identify IL-17-expressing cells in vivo. In spleen, in contrast to lamina propria, only a minor population of CD4+CD25−CD62L−CD44hi memory T cells and a very small percentage of natural killer T (NKT) cells expressed RFP upon restimulation (Figure S2C). Moreover, a substantial portion of γδ T cells was RFP+ (Figure S2C). These results suggest not only that our reporter mice can be used to characterize various IL-17-expressing T cells, but also that γδ T cells may constitute a major source of IL-17 and IL-17F cytokines in vivo.

To analyze Th17 cells generated under pathological conditions, we immunized Il17frfp and wild-type mice with myelin oligodendrocyte glycoprotein (MOG) peptide emulsified in complete Freund’s adjuvant (CFA). Five days later, splenocytes and draining lymph node cells were harvested from the immunized mice and restimulated with MOG peptide for 24 hr. As assessed by FACS, RFP was expressed in about 1%–2% of the CD4+ cells from Il17frfp mice (Figure 1D), comparable to the frequency of IL-17- and IL-17F-secreting cells (data not shown). In wild-type mice, no RFP+ cells were observed.

To understand the characteristics of pathogenic Th17 cells, we induced experimental autoimmune encephalomyelitis (EAE) in Il17frfp and wild-type mice. When most of the mice reached clinic score 3, with a symptom of hind-leg paralysis, the central nervous system (CNS) infiltrates were isolated and analyzed for IL-17F-RFP expression. In the CNS infiltrates from Il17frfp mice, approximately 20% of CD4+ cells expressed RFP (Figure 1E). To further characterize these Th17 cells in the CNS, we sorted RFP+ and RFP− CD4+ T cells from the CNS infiltrates of Il17frfp mice by FACS and performed gene expression analysis by real-time RT-PCR. The RFP+ cells from the CNS highly expressed mRNA for Th17-specific genes Il17a, Il17f, Il22, Il23r, and Rorc (Figure 1F). RFP− cells highly expressed Ifng and Tbx21, correlating with a large population of IFN-γ-secreting cells in the CNS of EAE mice (data not shown). Thus, Il17frfp reporter sensitively and faithfully marked Th17 cells in vitro and in vivo.

Analysis of Treg and Th17 Cell Development with an IL-17F- and Foxp3 Dual-Reporter Mouse
To investigate the relationship between Th17 and iTreg during T cell activation, we crossed Il17frfp with Foxp3frfp reporter mice (Fontenot et al., 2005) and produced an Il17frfpFoxp3frfp dual reporter. Naive (CD44hiCD62L−) CD4+ T cells were activated with anti-CD3 and anti-CD28 in the presence of IL-2 under iTreg (TGF-β, anti-IL-4, and anti-IFN-γ) or Th17 (TGF-β and IL-6) conditions for 1–4 days. IL-17F-RFP versus Foxp3-GFP expression was assessed daily by FACS. On day 1, Foxp3 expression was weakly induced in cells activated under either iTreg or Th17 conditions, and there was no cell expressing RFP (Figure 2A). On day 2, GFP+ cells were markedly increased in both conditions, and RFP-expressing cells started to appear under the Th17 culture condition. Interestingly, under the Th17 condition, approximately one-third of Foxp3-GFP+ cells also express RFP (Figure 2A), indicating that iTreg and Th17 cell differentiation can be simultaneously induced, at least in a portion of the activated T cells. On days 3 and 4, GFP+ cell numbers were drastically reduced, whereas percentage of RFP+GFP− cells was greatly increased. The presence of exogenous IL-2 did not affect the kinetics of RFP and GFP expression (Figure S3A). Moreover, on days 2 and 3, GFP+ cells did not exhibit increased apoptosis as examined by Annexin V staining (Figure S3B), suggesting that the Foxp3-GFP+ cells on day 2 in this culture did not preferentially undergo cell death. Compared with the Th17 condition, under the iTreg condition, although

Immunity 29, 44–56, July 18, 2008 ©2008 Elsevier Inc. 45
IL-17 expression was not detected (data not shown), weak RFP expression was found on day 2 and more substantially on day 3 in both GFP+ and GFP/C0 populations but it was greatly reduced on day 4 (Figure 2A). For further analysis of the RFP+GFP+ cells associated with iTreg cell differentiation, GFP+RFP/C0 and GFP+RFP+ cells were sorted on day 3 from the iTreg culture and examined by real-time RT-PCR for their gene expression. RFP+ cells expressed similar amounts of Foxp3 as RFP/C0 cells but markedly upregulated expression of Th17-specific genes IL-17, IL-17F, RORγt, and RORα (Figure 2B), supporting a dual program in these cells. These results indicate that under both Th17 and Treg cell conditions, Foxp3 and IL-17F coexpressors were induced transiently in some T cells before they were terminally differentiated into single producers, supporting the intimate relationship of Treg and Th17 cells during their development.

We then asked whether this RFP+GFP+ population or state also exists in the immune response in vivo. In naive Il17frfp–Foxp3gfp mice, splenic and laminal propria CD4+ T cells contained RFP and GFP single-positive cells; very few, if any, double-positive cells were observed (Figure 2C). For analysis of the regulation of T cell differentiation in immune responses, Il17frfp–Foxp3gfp dual-reporter and wild-type mice were immunized with MOG in CFA, and IL-17F-RFP and Foxp3-GFP were detected by FACS after MOG ex vivo restimulation. In comparison to CD4+ T cells from wild-type mice, about 1% of RFP+GFP+ Th17 cells and 4% of GFP+RFP+ Treg cells were observed in the dual-reporter mice after the immunization (Figure 2C). A small but detectable percentage (less than 0.1% of total CD4+ T cells and approximately 7%–8% of RFP+ cells) of cells expressed both RFP and GFP (Figure 2C), suggesting that Th17 and Treg cells generated in vivo also share intrinsic common programs with those differentiated in vitro.

**TGF-β Signaling Requirements during Th17 and iTreg Cell Differentiation**

TGF-β regulates iTreg and, together with IL-6, Th17 cell differentiation, but the underlying signaling mechanism is unclear. For analysis of this, naive cells from C57BL/6 (B6) mice were...
differentiated toward Th17 cells for 5 days, and an inhibitor of TGF-βRI kinase activity, SB431542, was added at different time points during the Th17 cell differentiation. Inhibition of TGF-β signaling on day 0 or day 1 completely abolished IL-17 production (Figure 3A). Moreover, a 50% reduction in IL-17 production was observed after addition of the inhibitor on day 2, whereas no substantial inhibition was found on day 3 (Figure 3B). Similar to Th17 cell differentiation, TGF-β signaling was also required during the first 2 days after initiation of iTreg cell differentiation (Figure 3C). These data indicate that active TGF-β signaling is required during the first 2 days of Th17 and Treg cell differentiation.

TGF-β receptor activation induces activation and phosphorylation of Smad2 and Smad3, which then bind to Smad4 and translocate to the nucleus (Feng and Derynck, 2005). Therefore, we next investigated the role of Smad4 by using Smad4-deficient CD4+ T cells. Mice with Smad4 deletion in T cells were generated by breeding mice with floxed Smad4 (fl) alleles (Chu et al., 2004) with CD4-Cre mice (Lee et al., 2001). Deletion of the Smad4 gene in CD4+ T cells from Smad4(fl)/CD4Cre+ mice was confirmed by PCR (Figure S4A). Smad4(fl)/CD4Cre+ mice exhibit normal populations of CD4+ and CD8+ T cells, as well as nTreg cells in spleen, lymph nodes, and thymus (Figures S4B and S4C). Moreover, Smad4-deficient nTreg were as suppressive as wild-type nTreg (Figure 3D). The proliferation of naive CD4+ T cells from wild-type or Smad4(fl)/CD4Cre+ mice was inhibited by nTreg from either wild-type or Smad4(fl)/CD4Cre+ mice (Figure 3D). Thus, Smad4 is not required for nTreg cell development and suppressive activity or naive T cell suppression by nTreg cells. We next investigated whether Smad4 is required for iTreg or Th17 cell differentiation by stimulating naive Th cells under iTreg or Th17 conditions. Smad4-deficient Th cells showed reduced Foxp3 expression compared to wild-type T cells upon iTreg induction (Figure 3E). However, upon Th17 cell differentiation, comparable numbers of IL-17-producing cells were observed between Smad4-deficient and wild-type T cells (Figure 3F), indicating that Smad4 is differentially required for iTreg and Th17 cell differentiation. Further in vivo analysis showed no difference in IL-17, IL-17F, and IL-22 production between wild-type and Smad-4 deficient T cells after KLH immunization (Figure S4D). Thus, although active TGF-β signaling regulates both iTreg and Th17 cell differentiation, different downstream molecules may be utilized to regulate the development of these two T cell lineages.

Figure 2. Reciprocal Th17 and iTreg Cell Differentiation

(A) Naive T cells from Il17f(fl)/Foxp3gfp mice were activated in the presence of IL-2 under iTreg (TGF-β, anti-IL-4, and anti-IFN-γ) or Th17 (TGF-β and IL-6) cell conditions for 1–4 days. IL-17F-RFP and Foxp3-GFP expression was assessed daily by FACS. Data shown were repeated twice with consistent results.

(B) On day 3, RFP+ and RFP− subsets were sorted on a GFP− gate from the iTreg cell culture, and gene expression was assessed by real-time RT-PCR. Data shown were normalized to expression of a reference gene, Actb. The lower expression for each gene was referred as 1. The graph shows means ± SD.

(C) Magnetic activated cell sorting (MACS)-enriched splenic (SP) and laminal propria (LP) CD4+ CD25−, RORγt, and IL-23R mRNA in Th cells after addition of SB431542 on days 0 and 1 (Figure 3B). Similar to Th17 cell differentiation, TGF-β signaling was also required during the first 2 days after initiation of iTreg cell differentiation (Figure 3C). These data indicate that active TGF-β signaling is required during the first 2 days of Th17 and Treg cell differentiation.

Regulation of Th17 Cell Differentiation by Foxp3

Because TGF-β induces the expression of Foxp3, we next assessed Foxp3 function in Th17 cell differentiation. First, we overexpressed Foxp3 in T cells by retroviral transduction. Naive CD4+ T cells from OT-II mice were activated with Ova peptide and irradiated splenic APCs under Th17 conditions. On day 1, activated T cells were infected with bicalutropic retroviruses containing an IRES-GFP. Four days after infection, IL-17F and IL-22 production between wild-type and Foxp3-expressing T cells was assessed by FACS after MOG restimulation. We found that Foxp3 overexpression greatly decreased the percentage of IL-17-secreting cells (Figure 4A). We then sorted GFP− and GFP+ cells from the above experiment, and their gene expression profiles were assessed with real-time RT-PCR. In comparison with cells infected with the control virus, Foxp3 overexpression greatly reduced IL-17, IL-17F, and IL-21 mRNA expression, whereas RORγt and RORα expression remained the same (Figure 4B). These
results indicate that Foxp3 inhibits Th17 cell differentiation and suggest that it might not inhibit RORα or RORγ mRNA expression but rather interfere with their function.

For analysis of the regulation of RORα and RORγt function by Foxp3, EL-4 cells were transfected with an Il17a-promoter-CNS2 luciferase reporter vector (Yang et al., 2008b) in the presence or absence of RORα or RORγt with or without Foxp3-expressing vector. Whereas RORα or RORγt alone induced luciferase activity, coexpression of Foxp3 markedly reduced their activity (Figures 4C–4F and Figures S5D–S5F). Because neither the IL-17 promoter nor the CNS2 element contains a detectable Foxp3-binding site, we analyzed whether Foxp3 DNA binding or homodimerization is required for its ability to suppress RORα or RORγt function. Foxp3ΔFKH, a Foxp3 mutant lacking the forhead domain but with the SV40 nuclear localization sequence (Lee et al., 2008), or Foxp3ΔE250, a Foxp3 mutant that possesses a single amino acid deletion in the leucine-zipper domain and thus cannot homodimerize or bind to DNA well (Chae et al., 2006), was coexpressed with RORγt. These two mutants were found to still inhibit RORγt-driven luciferase activity (Figure 4C). Foxp3ΔE250 and Foxp3ΔFKH also inhibited Th17 cell differentiation in primary T cells (data not shown). Furthermore, Foxp3 also directly inhibited RORγt activation of a RORE reporter in a dose-dependent manner (data not shown).
data together indicate that Foxp3 overexpression inhibits RORγt activity independently of Foxp3 homodimerization or DNA binding.

Nuclear receptors bind to coactivators or corepressors through interaction between the AF2 domains of the nuclear receptors with LxxLL motifs in coactivators and/or corepressors. To understand how Foxp3 inhibits ROR function, we utilized a mammalian two-hybrid system, in which luciferase reporter activity is activated upon binding of RORγ to an LxxLL-containing peptide EBIP96 derived from SRC-1 coactivator (Kurebayashi et al., 2004). Interestingly, Foxp3 inhibited, in a dose-dependent manner, the binding of RORγ to the LxxLL-containing peptide (Figure S5A), indicating that Foxp3 may interfere with the association of RORγ with its coactivator. Given that Foxp3 contains an LQALL sequence in its second coding exon, we hypothesized that Foxp3 might interact with both RORs and RORγt and

---

**Figure 4. Foxp3 Inhibits Th17 Cell Cytokine Induction by Antagonizing RORγt Function**

(A) FACS-sorted naive OT-II T cells were activated under Th17 conditions and infected with an IRES-GFP-containing bicistronic retrovirus expressing Foxp3 or a vector control virus. IL-17- and Foxp3-expressing cells were measured by intracellular staining on the GFP+ and GFP population. The experiments were repeated at least three times with similar results.

(B) GFP+ and GFP- cells were sorted from (A) and restimulated for 4 hr with anti-CD3. mRNA expression of indicated genes was analyzed by real-time RT-PCR. The data shown were normalized to expression of a reference gene, Actb. The lowest expression for each gene was referred as 1. * p < 0.05, t test.

(C–F) EL-4 cells were transfected with a vector containing the firefly luciferase gene under the control of the Il17a promoter-CNS2 region, a vector expressing Renilla luciferase, and IRES-GFP-containing bicistronic vectors expressing RORγt, Foxp3 wild-type (WT), or various Foxp3 mutants, or vector alone. Luciferase activity was determined and normalized to Renilla luciferase. Values were also normalized to vector alone. The data represent at least four independent experiments with consistent results. * p < 0.05, t test.

In (B)–(F), the graphs show means ± SD.

(G) Naive OT-II T cells were activated under Th17 conditions and infected with indicated viruses. IL-17 expression was analyzed by intracellular staining on either GFP+ or GFP- gate.

(H) Naive WT or Scurfy OT-II T cells were stimulated with the indicated cytokines and neutralizing antibodies. Four days later, cells were assessed for IFN-γ and IL-17 production by intracellular staining. The data represent at least three independent experiments with consistent results.
compete with coactivators for ROR binding. We therefore examined the interaction of RORα with wild-type Foxp3 and several Foxp3 mutants by using coimmunoprecipitation. Although Foxp3 and RORα were found to associate when they were coexpressed in 293T cells, a Foxp3 mutant carrying a mutation in an LQALL motif (LL-AA mutant) exhibited a greatly decreased association with RORα (Figure SSB). In addition, a mutant Foxp3 containing only amino acids encoded by exons 1 and 2, which include the LQALL motif but no DNA binding or dimerization domain, inhibited RORγt transcriptional activity (Figure SCC), suggesting that LQALL in Foxp3 may inhibit RORγt interaction with a coactivator.

We further tested the function of Foxp3 LQALL motif by use of the LL-AA mutant. In the mammalian two-hybrid system, the Foxp3 LL-AA mutant had reduced ability to inhibit the binding of RORγt to EBIP96, compared to Foxp3 wild-type (Figure SSA). To evaluate the functional implication of this decreased inhibitory activity by the Foxp3 LL-AA mutant, we analyzed whether lack of the LxxLL domain impairs Foxp3 ability to inhibit activation of IL-17 transcription by RORs. We observed a non-statistically significant dose-dependent downregulation of luciferase activity by Foxp3 LL-AA mutant when coexpressed with RORγt or RORα (Figure 4D and Figure SSD). Thus, these results indicate that the Foxp3 LxxLL domain is important for binding to RORs, but lack of this domain inhibits but does not completely abolish Foxp3-mediated interference of ROR activity.

Foxp3 has been previously shown to bind to TIP60 and HDAC7 (Li et al., 2007). To further explore which additional domain of Foxp3 might be required for its inhibitory activity on RORs, we utilized a Foxp3 Δ105-190 mutant that does not bind to TIP60-HDAC7 complex (Li et al., 2007). Interestingly, although this mutant binds to RORα well when they were coexpressed in 293T cells (Figure SSB), the ability of Foxp3 to inhibit transcriptional activity of RORγt was partially reversed by lack of TIP60-HDAC7-binding domain (Figure 4E and Figure SSE). Moreover, lack of both LxxLL and TIP60-HDAC7 domains completely impaired Foxp3 inhibition of RORγt or RORα transcriptional activity (Figure 4F and Figure SFF). For further demonstration of the role of these domains in inhibition of Th17 cell differentiation, naive OT-II cells were infected with Foxp3 constructs under Th17-polarizing conditions, and IL-17 production was evaluated by intracellular staining. Overexpression of wildtype, LL-AA, or Δ105-190 Foxp3 mutants greatly decreased the percentage of IL-17-secreting cells compared to cells infected with vector alone (Figure 4G). However, Foxp3 lacking both the LxxLL and TIP60-HDAC7 domains was not able to inhibit IL-17 production (Figure 4G), further demonstrating that Foxp3 inhibits the activity of RORα and RORγt by direct binding with its LQALL domain and/or by recruiting the TIP60-HDAC7 complex.

To further assess the function of Foxp3 in Th17 cell differentiation, we bred OT-II T cell receptor (TCR) transgenic mice with Scurfy mice, which have a point mutation in Foxp3 gene. Naive CD4+ T cells from wild-type or Scurfy OT-II mice were stimulated with Ova peptide and irradiated splenic APCs in the presence of different cytokine stimuli. Similar to wild-type T cells, Scurfy OT-II cells did not produce IL-17 in the present of TGF-β alone (Figure 4H, Figure S6A), indicating that Foxp3 deficiency was not sufficient to convert iTreg into Th17 cells and suggesting that IL-6 signaling is required for Th17 cell differentiation and does not just function by suppressing Foxp3 expression. When they were activated in the presence of TGF-β and IL-6, reduced production of IL-17 and IL-17F and enhanced IFN-γ was observed in the Scurfy T cells (Figure 4H, Figure S6A). However, addition of blocking antibodies to IFN-γ and IL-4 together with TGF-β and IL-6 resulted in comparable amounts of IL-17 and IL-17F production in wild-type and Scurfy Th cells (Figure 4H, Figure S6A). Real-time PCR analysis also indicated decreased expression of IL-17, IL-17F, and RORγt mRNA in Scurfy-deficient Th cells compared to wild-type counterparts when they were activated by TGF-β and IL-6, whereas blocking antibodies to IL-4 and IFN-γ restored their IL-17, IL-17F, and RORγt mRNA expression (Figure S6B). Taken together, these results indicate that lack of Foxp3 expression in T cells leads to increased Th1 cell differentiation and does not enhance Th17 cell differentiation. The latter is probably due to an inhibitory effect by IL-6 on Foxp3 expression and function during Th17 cell differentiation.

**Conversion of iTreg to Th17 Cells**

Because TGF-β induces Foxp3 on its own whereas IL-6 overrides this differentiation process and skews T cells toward Th17 lineage, we next analyze whether IL-6 is able to inhibit precommitted Foxp3-mediated Treg programs. Naive CD4+ T cells from Foxp3-GFP reporter mice were activated together with TGF-β, IL-2, and neutralizing antibodies against IL-4 and IFN-γ by direct binding to TGF-β and Foxp3 expression was sustained (Figure 5A). In the presence of TGF-β, IL-6 alone or in combination with IL-1 and IL-23, enhanced Foxp3 downregulation but only slightly increased IL-17 production (Figure 5A). However, when we stimulated iTreg cells with TGF-β, Foxp3 expression was sustained (Figure 5A). In the presence of TGF-β, IL-6 alone or in combination with IL-1 and IL-23 markedly downregulated Foxp3 expression and increased IL-17 production (Figure 5A). Real-time RT-PCR analysis of other Th17-specific genes demonstrated substantially enhanced expression of IL-22, IL-23R, and RORγt mRNA in iTreg cells stimulated with IL-6, IL-1, and IL-23 (Figure 5B). However, the expression of these genes was not significantly increased in the presence of TGF-β (Figure 5B). Thus, these results indicate that the Treg program is turned off by IL-6 and that iTreg cells can be reprogrammed to Th17 cells in the presence of TGF-β and IL-6.

Recently, all-trans retinoic acid (RA) was shown to inhibit the induction of proinflammatory Th17 cells but to promote anti-inflammatory Treg cell differentiation (Mucida et al., 2007). We thus asked whether RA affects redifferentiation of Treg cells toward Th17 cells. Naive CD4+ T cells from Il17frfpFoxp3gfp mice were activated with TGF-β and IL-2 in the presence or absence of RA. As reported, inclusion of RA enhanced Foxp3 induction (data not shown). Three days later, GFP+RFP+ cells were sorted and restimulated in the presence of TGF-β, IL-6, IL-1, and IL-23. Although pretreatment with RA did not affect Foxp3 downregulation, it prevented the upregulation of RFP (IL-17F) and IL-17 expression (Figure 5C). Thus, although iTreg cells developed in the presence of RA were still susceptible to

Interplays of Treg and Th17 Programs

---

Foxp3 downregulation, they were resistant to induction of the Th17 program.

**Cytokine-Driven Conversion of nTreg Cells into Th17 Cells**

Because iTreg cells, even 5 days after differentiation, can be reprogrammed to Th17 cells, we asked whether nTreg cells could be converted. FACS-sorted CD4+CD25+ T cells from B6 mice, which contained more than 99% Foxp3-expressing T cells (data not shown), were activated with plate-bound anti-CD3 and anti-CD28 in the presence of IL-6 for 4 days. Addition of IL-6 to nTreg cells resulted in expression of IL-17 and downregulation of Foxp3 expression (Figure 6A). Similarly, when nTreg cells from the IL-17F-RFP reporter mice, which did not express RFP after sorting (data not shown), were cultured as above, RFP was induced (Figure 6B). This finding indicates that IL-17F was also induced by IL-6 in nTreg cells. Next, for determination of whether IL-17-IL-17F-expressing T cells were suppressive, RFP+ and RFP− cells (Figure 6B) were FACS sorted and subjected to a suppression assay. Similar to nonmanipulated nTreg cells, RFP− cells inhibited the proliferation of naive T cells (Figure 6C). However, IL-17F-RFP+ cells exhibited greatly reduced suppressive activity.

The above experiments suggest that nTreg cells can be reprogrammed and redifferentiated into Th17 cells. To understand whether such a regulation exists in vivo, we purified CD4+GFP+ Treg cells from Foxp3 reporter mice (CD45.2+) and mixed them at 1:10 ratios with CD4+CD25− cells from CD45.1+ congenic mice before transferring them into Rag1−/−/− recipients. More than 99% of sorted GFP+ cells were stained by an anti-Foxp3 antibody (Figure 6D). Because some nTreg cells are reactive with MOG peptides (Korn et al., 2007), the recipients were immunized with MOG peptide in CFA. Five days later, CD45.1+ and CD45.2+ CD4+ T cells were analyzed for Foxp3 and IL-17 expression after restimulation with PMA plus ionomycin or MOG peptide. As expected, substantially IL-17 expression was detected in CD45.1+ cells, indicating that the immunization protocol was successful (Figure 6D). However, in CD45.2+ populations, there was significant downregulation of Foxp3 expression (Figure 6D). In addition, IL-17 expression was detected in Foxp3− cells (Figure 6D). When cells were restimulated with PMA plus ionomycin, Foxp3 and IL-17 dual expressers were also observed (Figure 6D). This result indicates that in the presence of inflammatory signals, nTreg cells can differentiate into Th17 cells in vivo.

**Regulation of nTreg Conversion to Th17 Cells**

We further examined the regulation of Treg cell differentiation into Th17 cells by other cytokines by using Treg cells purified from Foxp3-GFP reporter mice. In addition to IL-6, IL-21 exerted similar regulation but was less potent (Figure 7A). IL-1 alone induced a small percentage of IL-17-producing cells but did not
markedly change the expression of Foxp3. However, in the presence of IL-6 or IL-21, IL-1 further enhanced the percentages of IL-17-positive cells, without any additional impact on Foxp3 expression (Figure 7A). No synergistic effect by IL-23 was observed (Figure 7A). Because nTreg cells produce TGF-β, we next examined whether TGF-β was required for the IL-6-mediated conversion of nTreg to Th17 cells. Addition of a blocking antibody to TGF-β abolished IL-17 expression induced with IL-6, IL-1, and IL-23 but did not enhance Foxp3 expression (Figure 7A). Thus, although TGF-β, IL-6, IL-21, and IL-1 regulate the induction of IL-17-producing cells, IL-6 seems most potent and unique in downregulating Foxp3 expression.

nTreg cells from mesenteric lymph nodes could be also converted into Th17 cells upon activation in the presence of IL-6, IL-1, and IL-23 (Figure S7A). To rule out the possibility that the converted cells were iTreg generated in the periphery, we isolated CD4+CD25+ T cells from B6 mice were cultured in triplicate wells with or without CD4+CD25+ T cells from B6 mice or the sorted RFP+ or RFP− cells in the presence of irradiated APCs and 2 μg/ml anti-CD3. Proliferation was assayed 72 hr later by adding [3H]-thymidine to the culture for the last 8 hr. The graph shows means ± SD. The data represent at least two independent experiments with consistent results. To better characterize the conversion of nTreg cells to Th17 cells, we utilized Treg cells from Il17frfpFoxp3gfp double-reporter mice. FACS-sorted CD4+GFP+ cells from these mice were activated with plate-bound anti-CD3 and anti-CD28 in the presence of indicated cytokines. Downregulation of Foxp3 expression was detected on day 1 and was further enhanced during the next 3 days (Figure 7B). RFP expression was observed on day 2 and optimally induced on days 3 and 4. Interestingly, similar numbers of IL-17F single-positive and IL-17F+Foxp3+ cells were observed on days 2 and 3; however, on day 4, the majority of IL-17F-producing cells did not express Foxp3-GFP (Figure 7B). For further characterization of these populations, IL-17F and Foxp3 single-positive cells were FAC sorted, and the expression of Th17 and Treg lineage-specific genes were analyzed by real-time RT-PCR. IL-17F-RFP single-positive cells expressed higher amounts of IL-17, IL-17F, IL-21, IL-23R, and RORγt mRNA than did Foxp3-GFP single-positive cells (Figure S8). Interestingly, Foxp3-GFP+ cells also upregulated RORγt, although they did not express Th17 markers, suggesting that Foxp3 repressed the function of RORγt in these cells. Thus, this result indicates that converted IL-17F-producing cells have the same phenotype as Th17 cells.

To determine whether STAT3, RORγt, and RORα are required for conversion of nTreg cells into Th17 cells, we first bred STATfl/fl mice with CD4-Cre mice, and we observed efficient deletion of STAT3 in T cells (data not shown). FACS-sorted CD4+CD25+ T cells from STAT3- and RORγt-deficient (Kurebayashi et al.,...
mice (the latter is deficient in all RORγ isoforms including RORγt) and from Rorasg/sg and Rora/sg/sgRorc/C0/C0 mice (Yang et al., 2008b) and their appropriate controls were stimulated with plate-bound anti-CD3 and anti-CD28 in the presence of various cytokines, and Foxp3 and IL-17 expression were determined by intracellular staining. STAT3-deficient nTreg cells failed to downregulate Foxp3 expression or express IL-17 (Figure 7C). In contrast, Rorc/C0/C0 nTreg cells downregulated Foxp3 expression but only expressed very low amounts of IL-17 when compared to their controls (Figure 7D). Compared to RORγ deficiency, RORα mutant T cells exhibited moderate reduction in IL-17 expression but normal Foxp3 downregulation (Figure S9). T cells defective in both RORα and RORγ were also able to downregulate Foxp3 but had complete IL-17 deficiency (Figure 7D). Thus, these data indicate that although STAT3, RORγt, and RORα are all required for IL-17 expression, Foxp3 downregulation is regulated by STAT3, but not by RORγt or RORα.

Because IL-17F-RFP-Foxp3-GFP− cells expressed IL-21 (Figure S8), we investigated whether this cytokine is required for Th17 induction in nTreg cells. FACS-sorted CD4+CD25+ T cells from IL-21-deficient mice and their appropriate controls were stimulated in the presence of indicated cytokines. Four days later, cells were assessed for Foxp3 and IL-17 expression by intracellular staining. Numbers in quadrants represent the percentages. The data represent at least three independent experiments with consistent results.

**DISCUSSION**

In this study, we have investigated the molecular interactions of the Treg and Th17 genetic programs (Figure S10). Using an
IL-17F-RFP reporter mice bred with a Foxp3-GFP reporter, we found the presence of a RFP*GFP* transient phase upon T cell activation in vitro and in vivo, indicating that both Th17 and Treg cell programs could be simultaneously induced in some T cells before they are terminally differentiated into either lineage. On the one hand, Foxp3, induced by TGF-β, plays an important role in the development, maintenance, and induction of regulatory T cells. Our mutagenesis analysis reveals that Foxp3 could compete with coactivator binding to RORs via two independent and nonexclusive mechanisms. Moreover, we found that Scurfy T cells, compared to their wild-type counterparts, exhibited reduced expression of Th17 cytokines and RORα and RORγt when stimulated with TGF-β and IL-6; this reduced expression was associated with increased Th1 cell differentiation. However, when IFN-γ and IL-4 were lowered under the same conditions, restoration of Th17 cytokines and RORγt was observed. Therefore, lack of Foxp3 expression in T cells results in enhanced Th1 cell differentiation, but Foxp3, although transiently induced in some T cells undergoing Th17 development, is not required for Th17 cell lineage differentiation. Furthermore, because Scurfy T cells did not spontaneously develop into Th17 cells in the presence of TGF-β, it suggests that TGF-β signaling is not sufficient to drive Th17 cell differentiation. STAT3 downstream of IL-6 may be also required, which does not merely function by downregulating Foxp3. Our results thus further support the synergy of TGF-β and IL-6 in Th17 cell differentiation.

IL-6 inhibits TGF-β-dependent Foxp3+ Treg cell induction (Bettelli et al., 2006). Our current study also indicates that IL-6 can reprogram fully differentiated iTreg and nTreg cells and redifferentiate them toward the Th17 lineage. By using reporter mice for Foxp3 and IL-17F, we found that the resulting cells express Th17-specific genes and lack suppressive function. This action by IL-6 is synergized by IL-1 and requires TGF-β. However, although TGF-β, IL-6, IL-21, and IL-1 regulate the induction of IL-17-producing cells, IL-6 seems most potent in downregulating Foxp3 expression. Terminally differentiated cells have been shown to be able to dedifferentiate and redifferentiate. For example, it was recently reported that mature B cells, when the Pax5 gene was deleted, were able to redifferentiate into T cells (Cobaleda et al., 2007). Interestingly, it was previously observed that deletion of the Foxp3 gene in mature nTreg cells resulted in loss of suppressive function and upregulation of IL-17 and IL-21 expression (Williams and Rudensky, 2007), suggesting that the suppression of Th17 gene expression and the maintenance of Treg programs both require Foxp3. Unlike these two cases, here we observe the proinflammatory cytokine milieu in both de- and redifferentiation of T cells. Our results are consistent with recent work by Xu et al., who found that Treg cells convert to Th17 cells when cultured with IL-6 in the absence of TGF-β (Xu et al., 2007). These studies not only indicate the plasticity of Th cell differentiation programs but also have important implications. First, they suggest an alternative source of Th17 cells in vivo, i.e., derived from Foxp3+/− nTreg and iTreg cells. This pathway is potentially problematic because many Treg cells have autoreactive specificities (Hsieh et al., 2004). Second, in future therapy using Treg cells against autoimmune diseases, suppression of inflammatory cytokines, especially IL-6, would be needed simultaneously to prevent them from differentiating into pathogenic Th17 cells.

How STAT3 mediates Foxp3 downregulation by IL-6 remains to be determined. IL-6 induced Foxp3 mRNA downregulation in nTreg cells 24 and 48 hr after treatment (data not shown). In addition, we also found that in T cells transduced with Foxp3-expressing retroviruses, i.e., with exogenous promoters and untranslated regions, IL-6 downregulated Foxp3 protein expression (data not shown). Regardless of which mechanism, this important regulation will unleash the inhibitory function of Foxp3, thus allowing Th17 cell differentiation to occur. It is of note that although Foxp3 strongly inhibits Th17 cell differentiation, substantial number of T cells coexpressed Foxp3 and IL-17 and IL-17F in the early phase after IL-6 treatment. IL-17 and IL-17F expression was dependent on RORγt and RORα. How RORα and RORγt overcome Foxp3 expression in these cells remains to be understood. It is not clear at this stage whether Foxp3 and IL-17 dual-expresser cells are bipotential.

In summary, we demonstrate in this study molecular mechanisms of antagonistic regulation of Treg and Th17 programs, both of which depend on TGF-β. In addition, our data indicate the plasticity of nTreg and iTreg cells and the transcriptional pathways that convert them to the Th17 program. These results may be beneficial in our further understanding on the genetic programs underlying Th cell differentiation and maintenance, and have implications in immunotherapy. One may consider enhancing Treg generation and function in autoimmunity while converting regulatory T cells to effector T cells in cancer patients.

**EXPERIMENTAL PROCEDURES**

**Mice**

C57BL/6, Rag1-deficient, and B6.SJL (CD45.1) mice were purchased from Jackson Laboratories. Smad4fl/fl mice were kindly provided by M. Matzuk with permission of E. Robertson (Chu et al., 2004), and these mice as well as Stat3fl/fl mice were bred with CD4-Cre mice provided by C. Wilson. Scurfy mice obtained from the Jackson Lab were crossed with OT-II mice, and mice at 4 weeks of age were used. IL-21 knockout mice and Rorc−/−, Rorasg/sg, and Roraax3/Roraax3Rorc−/− mice were described previously (Kurebayashi et al., 2000; Nurieva et al., 2007; Yang et al., 2008b). Il17f rfp reporter was generated by insertion of an IRES-mRFP-polyA cassette into the exon 2 of the Il17f gene (Yang et al., 2008a) and maintained on a 129xDb6 Fl background. Mice were housed in the specific pathogen-free (SPF) animal facility at M.D. Anderson Cancer Center, and the animal experiments were performed at the age of 6–10 weeks with protocols approved by Institutional Animal Care and Use Committee.

**T Cell Differentiation**

CD4+CD25−CD62L+CD44− cells were FACS sorted and stimulated and analyzed as described (Nurieva et al., 2007; Yang et al., 2007). All-trans retinoic acid was purchased from Sigma and used at a 100 nM/ml concentration. Gene expression was examined with a Bio-Rad iCycler Optical System with the iQTM SYBR green real-time PCR kit (Bio-Rad Laboratories). The data were normalized to Actb reference. The primers were previously described (Nurieva et al., 2007; Yang et al., 2007).

**MOG Immunization and Induction of EAE**

Female mice at 5–8 weeks of age were immunized subcutaneously at the dorsal flanks with 150 μg of MOG35–55 peptide emulsified in CFA. Five days later,
cells from spleens and draining lymph nodes of the immunized mice were iso-
lated and restimulated with MOG for 24 hr, and RFP and GFP expression was
assessed by flow cytometry. Induction of EAE was as described (Yang et al.,
2008b).

**Transcription-Reporter Assay**

ROTY, ROFx, wild-type Foxp3, Foxp3ΔE250, Foxp3ΔFKH/NLS, Foxp3LL-AA,
Foxp3Δ105-190, or Foxp3LL-AA Δ105-190 were cloned into bicistronic retro-
 viral vector p3FP-RV provided by K. Murphy that contains IRES-regulated
GFP. The expression vectors were transfected into EL-4 cells with a luciferase
construct containing IL-17 minimal promoter with CN57 element (Yang et al.,
2008b). The dual-luciferase reporter system (Promega) was used to assay
Firefly and Renilla luciferase activity in each sample. Renilla luciferase was
used to normalize transfection efficiency and luciferase activity.

**Two-Hybrid and RORE-Reporter Assay**

CHO cells were cotransfected with 0.1 μg of a luciferase reporter, 0.05 μg of a
RORY-expressing vector, 0.1 μg of an LXXLL-motif-encoding vector
pM-EBIP96, and Foxp3-expressing vectors as indicated with Fugene 6 trans-
faction reagent (Roche, Indianapolis, IN). The luciferase reporter was (UAS)L-
Luc, containing five copies of the GAL4 upstream-activating sequence (UAS)
or (RORE)Luc, and the ROXY-expressing vector is VP16-RORX or
pZeoS-V-ROXY. Cells were incubated for 40 hr, and then luciferase activity was
analyzed with a luciferase kit (Promega). Transfection efficiency was nor-
malized by β-galactosidase activity.

**Coimmunoprecipitation**

Expression vectors encoding RORγt, wild-type, or mutant Foxp3 molecules
were transfected into 293 T cells. After 48 hr, cells were washed with
ice-cold PBS and lysed in ice-cold lysis buffer (50 mM Tris-HCl [pH 8.0],
120 mM NaCl, 1% Nonidet P-40, 4 mM EDTA, 50 mM NaF, 1 mM Na3VO4,
2 μg/ml aprotinin, 1 μg/ml leupeptin, 1 μg/ml pepstatin A). Lysates were ob-
tained by centrifugation and precleared with protein A-sepharose (Sigma-Ald-
rich) for 2 hr before 2 μg of anti-FLAG-M2 antibody (Sigma-Aldrich) was
added. After incubation, protein A-Sepharose was added and immunoprecipit-
ates were obtained by centrifugation. Equivalent amounts of protein from
whole-cell lysates or immunoprecipitates were analyzed by western blot using
anti-human and -mouse Foxp3 (eBioscience) or anti-FLAG-M2.

**Retroviral Transduction**

Naive CD4+CD25+CD62LhiCD44hi T cells from OT-II mice were FACs sorted
and activated with Ova peptide and irradiated wild-type splenic APCs in the
presence of Th17 conditions (TGF-β, IL-6, IL-23, anti-IL-4, anti-IFN-γ). Twenty-four
hours after activation, cells were infected by retroviruses expressing
Foxp3 or control empty vector (containing only IRES-GFP) and analyzed
4 days later as previously described (Yang et al., 2008b)

**In Vivo Conversion of Treg Cells**

CD4+GFP+ cells from Foxp3-GFP reporter mice (CD45.2+) were transplanted
into 293 T cells. After 48 hr, cells were washed with ice-cold PBS and lysed in
ice-cold PBS and lysed in ice-cold lysis buffer (50 mM Tris-HCl [pH 8.0],
120 mM NaCl, 1% Nonidet P-40, 4 mM EDTA, 50 mM NaF, 1 mM Na3VO4,
2 μg/ml aprotinin, 1 μg/ml leupeptin, 1 μg/ml pepstatin A). Lysates were ob-
tained by centrifugation and precleared with protein A-sepharose (Sigma-Al-
rich) for 2 hr before 2 μg of anti-FLAG-M2 antibody (Sigma-Aldrich) was
added. After incubation, protein A-Sepharose was added and immunoprecipit-
ates were obtained by centrifugation. Equivalent amounts of protein from
whole-cell lysates or immunoprecipitates were analyzed by western blot using
anti-human and -mouse Foxp3 (eBioscience) or anti-FLAG-M2.

**SUPPLEMENTAL DATA**

Supplemental Data include ten figures and can be found with this article online
at http://www.immunity.com/cgi/content/full/29/1/44/DC1/

**ACKNOWLEDGMENTS**

We thank A. Rudensky and R. Medzhitov for the Foxp3-GFP reporter mice, E.
Robertson for Smad4-/- mice, R. Tsien and R. Flavell for the mRFP cDNA,
E. Wieder and Y. Wan for help on FACS sorting and analysis, K. Murphy for
RV-GFP vector, and the members of the Dong lab for their help. The work is
supported by research grants from the National Institutes of Health (NIH:
AR05772 to C.D. and CA108454 to X.H.F.), an Intramural Research Program
of the National Institute of Environmental Health Sciences (NIEHS, NIH)
to A.M.J.), and the MD Anderson Cancer Center and the Gillson Longenbaugh
Foundation (to S.S.W.), R.N. is the recipient of a Scientist Development Grant
from the American Heart Association. X.H.F. and C.D. are Leukemia & Lym-
phoma Society Scholars. K.S. and C.D. are both Trust Fellows of the MD An-
derson Cancer Center. C.D. is a Cancer Research Institute Investigator and an
American Lung Association Career Investigator.
