Abnormal airway ion transport plays a central role in the pathogenesis of cystic fibrosis (CF) lung disease. Cytokines released in allergic airway inflammation on airway ion transport in vivo, we challenged BALB/c mice with a natural allergen, i.e. Aspergillus fumigatus extract (Af), by intratracheal instillation, and studied the effects on ion transport in freshly excised airway tissues in Ussing chambers, and on mRNA expression of the epithelial Na+ channel (ENaC) by real-time RT-PCR. Af challenge induced a robust allergic airway inflammation with elevated IL-13 and eosinophils in the airways. Amiloride-sensitive ENaC-mediated Na+ absorption was significantly reduced ($\Delta_{\text{isc}}$-amiloride = 22.2±3.2 μA/cm² vs. $\Delta_{\text{isc}}$-amiloride = 32±3.8 μA/cm², n=18–21 per group, P < 0.05) and Ca2+-activated (UTP-mediated) Cl− secretion was increased ($\Delta_{\text{isc}}$-amiloride = 72.8±11.0 μA/cm² vs. $\Delta_{\text{isc}}$-amiloride = 45.8±7.0 μA/cm², n=18–21 per group, P < 0.05) in lower airway tissues from allergen-challenged compared with naive mice. Moreover, allergic inflammation caused a significant reduction in α, β, and γENaC expression. We conclude that allergic inflammation inhibits ENaC-mediated Na+ absorption and enhances CaCC-mediated Cl− secretion thereby producing a hypersecretory phenotype in vivo. This could be of relevance for CF patients with confounding allergic airway disease including allergic bronchopulmonary aspergillosis.

In lung tissues of patients suffering from cystic fibrosis (CF), a hereditary disease caused by mutations in the membrane bound chloride channel CFTR, and in unaffected CF mice, we have detected an impaired accumulation of ceramide (Teichgraber et al., Nature Med 2008;14:382). Ceramide accumulation promotes an age-dependent recruitment of macrophages and neutrophils in lungs of unaffected CF mice which was abrogated by administration of amitrinylamine, a blocker of acid sphingomyelinase. Since endogenous glycolipids are known to trigger NKT cell function, this study supports that CFTR chloride mechanisms after 4h and 8h of treatment. We have demonstrated that AZM significantly decreased TNF-α induced NF-kB transcriptional activity in S9 but not in IB3−1 cell line.

Conclusion: Our study demonstrates that azithromycin is not able to decrease inflammation in CF bronchial epithelial cells and suggests that CFTR chloride function may be involved in normal cells response to AZM.

Azithromycin is not able to decrease inflammatory process in cystic fibrosis human bronchial epithelial cells

V. Saint-Criq1, J. Jacquot1, A. Clement1, O. Tabary1, 1Inserm UMR-S 988, Hôpital St-Antoine, UPMC Univ. Paris 06, Paris, France

Objective: The aim of this study was to explore the effects of macrolides: azithromycin (AZM), clarithromycin (CAM) and erythromycin (EM) on molecular mechanisms involved during inflammation in bronchial epithelial cystic fibrosis (CF) cells.

Methods: Human CF bronchial epithelial (IB3−1) and CFTR-corrected bronchial epithelial cell lines (S9) were pre-treated 30 minutes with the macrolide (10 μg/ml) and TNF-α (10 ng/ml) was added for additional 16 h of culture. To confirm results, we have treated with the same protocol human bronchial gland cells (HBGI) isolated from non-CF patients with or without the CFTR inhibitor Inh-172 (10 μM, 72 h). IL-8 concentrations were evaluated in culture supernatants by ELISA and NF-kB pathway was investigated by a p65-luciferase plasmid at 4 h and 8 h of treatment.

Results: CAM and EM were able to modulate TNF-α induced IL-8 secretion. Interestingly AZM significantly reduced TNF-α induced IL-8 secretion in non-CF cells (S9 and HBG cells) but not in CF cells (IB3−1 and HBG cells treated with the CFTR inhibitor Inh-172). Next, we have investigated molecular mechanisms after 4 h and 8 h of treatment. We have demonstrated that AZM significantly decreased TNF-α induced NF-kB transcriptional activity in S9 but not in IB3−1 cell line.

Conclusion: Our study demonstrates that azithromycin is not able to decrease inflammation in CF bronchial epithelial cells and suggests that CFTR chloride function may be involved in normal cells response to AZM.

Weak anti-inflammatory effects of glucocorticoids on CF bronchial epithelial cells

C. Rebeyro1, L. Guillot1, V. Saint-Criq1, D. Ray2, A. Clement1, O. Tabary1, P. Le Rouzie1, 1UPMC, Univ Paris 06, Inserm UMR 938, Hôpital Saint-Antoine, Paris, France; 2School of Medicine, University of Manchester, Manchester, United Kingdom

Background: Lung dysfunction is the main cause of mortality in CF patients. Infection combined with inflammation lead to progressive degradation of respiratory epithelium. Glucocorticoids (GC) are powerful anti-inflammatory molecules commonly used to treat inflammation but with controversial efficiency among studies. Recent clinical trials showed that inhaled and oral corticosteroids have no significant effect on lung function or markers of inflammation. These results were confirmed in in vitro studies using cell lines and primary cell cultures from CF patients. Our project focuses on the key steps in GC activation pathway in bronchial epithelial cells to characterise the molecular basis of such dysregulation.

Methods: CF and non CF bronchial epithelial cell lines were incubated with IL-1β or TNF-α (10 ng/ml) at 4 h, 8 h, and 16 h with or without dexamethasone (dex, 1 μM). Rates of secreted IL-8 were assessed by ELISA 16h after treatment. To evaluate NF-kB or AP-1 activation at 4h and 8h, we transfected cells using plasmids containing NF-kB or AP-1 promoter coupled to luciferase.

Results: In presence of IL-1β, basal secretion of IL-8 was restored by dex at 16h in non CF cells, whereas CF cells barely respond. Other results showed there is no effect of dex on NF-kB activation at 8h in CF cells.

Conclusions: This study shows a lack of GC efficiency to decrease IL-8 secretion via NF-kB pathway in CF bronchial epithelial cells. Identify the origin of the GC resistance in CF will allow to adapt the anti-inflammatory treatments of patients.
