AND

BARBARA PARTEE

University of California at Los Angeles and System Development Corporation, Los Angeles, California 90024

A mathematical model of transformational grammars is presented which incorporates most current versions. Among other things, the model has a formal definition of transformations and a general scheme for ordering them. Numerous examples are given to illustrate the theory.

INTRODUCTION

One of the primary goals of linguistics is to find a suitable model of natural (human) language. Among the models proposed, one of them, the transformational grammar (abbreviated T-grammar) seems very promising and, in the past decade, has received considerable attention from linguists. At present, there are numerous alternative forms of the model under serious consideration. In fact, there is a noticeable lack of unanimity among linguists with respect to a number of aspects of the theory. As yet, no mathematical model has been given which encompasses most of these different versions of a T-grammar.¹ The purpose of

¹ A formalization of one particular version has been made in a forthcoming paper (Peters and Ritchie). Some extensions of this version and some consequences have been explored in Kimball (1967). A computer model has recently been proposed by Friedman (1968).
this paper is to propose one such mathematical model. In particular, a model is presented which appears to incorporate most current versions of transformational theory. As would be expected from linguistic experience, the model is general enough to yield all recursively enumerable sets as its generated languages. It appears likely that special natural restrictions on the model will yield many new types of formal languages of interest to the mathematician, linguist, and formal language theorist. In particular, because of the richness of the model, it seems reasonable to hope that appropriate restrictions will provide "grammars" for a number of families of formal languages introduced in the past few years by families of acceptors.

The paper is divided into four sections. In Section 1 we present a linguistic example to motivate the need for, and some underlying concepts of, T-grammars. In Section 2 we abstract some of the ideas of Section 1 and present a mathematical model of T-grammars. Section 3 contains some examples illustrating the ordering of T-rules and an example of a T-grammar in its entirety. Section 4 contains a number of possible restrictions on the general model. Taken in various combinations, these restrictions provide submodels which correspond to certain descriptions of T-grammars in the literature.

Stylistically, the paper has been written for the mathematical linguist, the mathematician, and the formal language theorist. In this way we hope to (1) make some of the issues more precise to the linguist and (2) make accessible to the mathematician and formal language theorist a number of definitions and concepts deeply embedded in the linguistic literature.

INFORMAL LINGUISTIC NOTIONS

As mentioned in the introduction, the purpose of the present paper is to obtain a formal definition of T-grammars. In this section we present an example to motivate the need for, and informally determine some features of, a T-grammar. The linguist will find nothing new here and we suggest he skip to Section 2.

Consider the following five English sentences:

(1') The dog chased the cat
(2') The cat ate the mouse
(3') The mouse was eaten by the cat

* One important exception is the notion of "syntactic features" described in Chomsky (1965) and included in most subsequent T-grammars.
(4') The cat that the dog chased ate the mouse

(5') The mouse was eaten by the cat that was chased by the dog

Using certain morphophonemic rules (of no concern to us here), sentences (1')–(5') can be derived from the following forms:

1. $the\ dog\ Past\ chase\ the\ cat\$'
2. $the\ cat\ Past\ eat\ the\ mouse\$
3. $the\ mouse\ Past\ be\ E,\ eat\ by\ the\ cat\$
4. $the\ cat\ that\ the\ dog\ Past\ chase\ Past\ eat\ the\ mouse\$
5. $the\ mouse\ Past\ be\ E,\ eat\ by\ the\ cat\ that\ Past\ be\ E,\ chase\ by\ the\ dog\$

In the remainder of this section, we shall construct a sample T-grammar, which generates "sentences" (1)–(5) (and other sentences as well).

Sentences (1) and (2) are generated by the following CF rules:

\[
S \rightarrow SS'$
\[
S' \rightarrow N_P A_{aux} V_P$
\[
V_P \rightarrow V_b N_P$
\[
N_P \rightarrow the\ N_n$
\[
A_{aux} \rightarrow T_{ns}$
\[
T_{ns} \rightarrow P_{act}$

The nonterminals $S'$, $N_P$, $A_{aux}$, $V_P$, $V_b$, $N_n$, and $T_{ns}$ abbreviate "sentence," "noun phrase," "verb auxiliary," "verb phrase," "verb," "noun," and "tense," respectively. The $S$ is the start symbol. The terminal symbols are $P_{act}$, the, chase, eat, dog, cat, mouse, and the boundary marker $. Clearly the rules generate (1) and (2) from $S$. If we were concerned only with sentences (1) and (2), then the above rules could be simplified. However, the rules as given provide linguistic structure needed to deal with sentences (3), (4), and (5).

The passive sentence (3) cannot be generated by these CF rules. Clearly we could add extra rules to generate (3). However, this would complicate the grammar considerably and would not indicate that (3)

---

3 The symbol $\$ is used as a sentence boundary marker.
4 We assume that the reader has a working knowledge of both context-sensitive (abbreviated CS) rules and context-free (abbreviated CF) rules.
5 The symbols "$P_{act}\$", "the", "chase," etc., are to be regarded as single symbols.
is related to (2). For linguistic purposes it is thus necessary to introduce a different kind of rule. The type of rule suggested by Chomsky (1957) and currently receiving much attention is the "transformation rule" (abbreviated "T-rule"). Roughly described, a T-rule is a procedure which operates on "structured" sentences to form other structured sentences. This leads to the notion of a postulated set of "simple" structured sentences (in the current example, the set of sentences generated by the CF rules), and T-rules to generate more complicated structured sentences from them.

To see how a T-rule is used to generate (3), let us consider how passive sentences are formed. Loosely described, a passive sentence is formed from its corresponding active sentence (e.g., (3) from (2)) by interchanging subject and object, adding "by" before the original subject, and changing the verb to passive form. Linguistically speaking, a sentence of the form

(6) $N_1 \overset{1}{\rightarrow} Wns \overset{2}{\rightarrow} VbN_p \overset{3}{\rightarrow} N_p$

is made into a passive sentence by converting it to

(7) $N_p \overset{1}{\rightarrow} T_n Vb by N_p \overset{2}{\rightarrow} X$.

In sentence (2), $N_1$ is "the cat," $T_n$ is "Past," $V_b$ is "eat," and $N_p$ is "the mouse." Restructuring (2) as above gives (3).

The mapping that converts sentences of the form (6) into sentences of the form (7) is a T-rule, called $T_{pas}$, which can be symbolically written as follows:

$T_{pas}:$ Domain statement: $X^{(1)} \overset{1}{\rightarrow} N_p \overset{1}{\rightarrow} T_n Vb N_p \overset{3}{\rightarrow} X^{(2)}$

$\alpha_1 \alpha_2 \alpha_3 \alpha_4 \alpha_5 \alpha_6 \alpha_7 \alpha_8$

Structural change statement: $\overset{1}{\rightarrow} 2 \overset{6}{\rightarrow} 4 \overset{3}{\rightarrow} 7 \overset{8}{\rightarrow}$

$N_p^{(1)}$ and $N_p^{(2)}$ are noun phrases, not necessarily identical to each other. $X^{(1)}$ and $X^{(2)}$ are variables representing arbitrary strings that are not necessarily identical to each other. In general, if a symbol occurs more than once in a domain statement, then each occurrence of the string it represents must be the same. In (6), each of the distinct symbols $X^{(1)}$ and $X^{(2)}$ is the empty string $\epsilon$. The domain statement specifies the form of the sentences to which the rule may be applied. The structural change

---

6. $E_n$ is a new terminal symbol which morphophonemically converts the verb following it to passive (i.e., past participle) form.
7. Actually, $N_p^{(1)}$ and $N_p^{(2)}$ are not noun phrases; they are symbols representing trees that generate noun phrases. The meaning attached to these symbols is discussed rigorously in C of Section 2.
8. An instance will shortly be given (Fig. 5), where neither $X^{(1)}$ nor $X^{(2)}$ is the empty string.
statement indicates the effect of the rule in a manner to be precisely explained in section two.

Since a T-rule applies to any sentence which can be parsed into the form given in the domain statement, in effect it applies to the tree associated with the CF derivation of the sentence. The T-rule maps that tree into a new one in accordance with the specifications of the structural change statement in a manner to be described in Section 2. In our example, the tree in Fig. 1 is mapped into the tree in Fig. 2.

As noted above, the result of applying a T-rule to a tree structure is again a tree structure. This allows an iteration of the procedure, that is, allows T-rules to be applied in sequence (in a manner more fully described later). Thus, for example, the “question” T-rule (not given in the present paper) can be applied to passive sentences.

Consider sentence (4). Intuitively, sentence (4) is a combination of sentences (1) and (2). It turns out that we need another CF rule and another T-rule to generate (4). Let us add to our CF rules the CF rule

\[ N_p \rightarrow N_n S' S. \]

The CF rules then generate

\( (4'') \) $ the cat $ the dog Past chase the cat $ Past eat the mouse $
FIG. 2.

```
the mouse

FIG. 3.

```

```
cat the dog

```

```
the cat

```
with the tree structure in Fig. 3. To derive (4), we need a T-rule which will convert the embedded sentence into a relative clause. The T-rule which accomplishes this is $T_{rel}$. In particular, $T_{rel}$ checks to see that there is a noun in the embedded sentence which is identical to the noun immediately preceding the embedded sentence. If there is, then the noun in the embedded sentence is replaced by "that"$^{11}$, and the word "that" moved to the front of the embedded sentence. In a manner similar to $T_{pas}$, $T_{rel}$ may be symbolically written as follows:

$T_{rel}$: Domain statement: $X^{(3)} N_n^{(3)} \vdash X^{(2)} \text{the } N_n^{(3)} X^{(2)} \vdash X^{(4)}$

$\alpha_1 \alpha_2 \alpha_3 \alpha_4 \alpha_5 \alpha_6 \alpha_7 \alpha_8 \alpha_9$.

Condition: $N_p$ generates $\alpha_6 \alpha_9$.

Structural change statement: $1-2-\text{that}-3-\emptyset-\emptyset-7-\emptyset-9$

The condition is a constraint on the domain of the T-rule. This par-

$^{11}$ The noun may also be replaced by "who" or "which," or it may even be deleted. For simplicity, only one case is considered here.
ticular condition means that in Fig. 3, $N_p$ generates $\alpha_2 \alpha_3$ with superscripts removed. The fact that the superscripts on the two occurrences of $N_n$ are the same means that the subtrees they generate must be the same.

In the structural change statement, $\emptyset$ denotes the empty tree (generating the empty string $\epsilon$). Its occurrence results in the deletion of the corresponding subtree designated by the domain statement. Thus, in this example, the second boundary marker $\$$ and the noun phrase "the cat" of the inner sentence are deleted (replaced by the empty tree), and "that" is substituted for the first boundary marker $\$$ of the inner sentence.

The terminal string associated with the tree in Fig. 3 generated by the CF rules satisfies the domain statement of $T_{rel}$ in the following way:

\[
\begin{array}{cccccc}
\text{\$ the cat } & \text{\$ the dog } & \text{P_{\text{eat}}} & \text{chase the cat } & \text{P_{\text{eat}}} & \text{the mouse } \text{\$} \\
X(1) & N_{n}^{(1)} & \$ & X(2) & \text{the } & N_{n}^{(1)} & X(3) & \$ & X(4)
\end{array}
\]

\[
\alpha_1 \alpha_2 \alpha_3 \alpha_4 \alpha_5 \alpha_6 \alpha_7 \alpha_8 \alpha_9
\]

Therefore, $T_{rel}$ can be applied to the tree in Fig. 3 to derive the tree in Fig. 4. The terminal string of the tree in Fig. 4 is the sentence (4).

![Fig. 5.](image-url)
Finally, consider sentence (5). Sentence (5) requires no additional rules. Its derivation involves $T_{\text{pas}}$, $T_{\text{rel}}$, and $T_{\text{pas}}$ as follows: The CF rules generate the tree in Fig. 5. The tree in Fig. 5 satisfies the domain statement of $T_{\text{pas}}$ as follows:

\[
\text{P_{\text{as}}} \text{t chase the cat P_{\text{as}}} \text{t eat the mouse}
\]

\[
\begin{array}{cccccc}
\alpha_1 & \alpha_2 & \alpha_3 & \alpha_4 & \alpha_5 & \alpha_6 & \alpha_7 & \alpha_8
\end{array}
\]

The $T_{\text{pas}}$ converts the tree in Fig. 5 into the tree in Fig. 6. The tree in Fig. 6 satisfies the domain statement of $T_{\text{rel}}$ as follows:

\[
\text{P_{\text{as}}} \text{t eat the mouse}
\]

\[
\begin{array}{cccccc}
\alpha_1 & \alpha_2 & \alpha_3 & \alpha_4 & \alpha_5 & \alpha_6 & \alpha_7 & \alpha_8
\end{array}
\]

The $T_{\text{rel}}$ converts the tree in Fig. 6 into the tree in Fig. 7. The tree in Fig. 7 satisfies the domain statement of $T_{\text{pas}}$ as follows:

\[
\text{P_{\text{as}}} \text{t eat the mouse}
\]

\[
\begin{array}{cccccc}
\alpha_1 & \alpha_2 & \alpha_3 & \alpha_4 & \alpha_5 & \alpha_6 & \alpha_7 & \alpha_8
\end{array}
\]

The $T_{\text{pas}}$ converts the tree in Fig. 7 into the tree in Fig. 8. The terminal string of the tree in Fig. 8 is sentence (5), so that the derivation is now complete.

In the above example, we included a set of CF rules as part of the T-grammar. Since our main concern in the sequel is with T-rules and their usage, we are interested in CF or CS rules only insofar as they define a set of trees which serve as input to the T-rules. Now the linguistic literature generally includes ordered sets of CF or CS rules, ordered, frequently, in quite special ways (Chomsky, 1965). Therefore, we shall simplify our discussion by assuming that part of the T-grammar consists of a "base," i.e., set of finite trees. We shall not be concerned with the mechanism that generates this set of trees.

In summary, then, the above example illustrates the utility of a gram-
Fig. 6.

Fig. 7.
mar with the following features:

(1) The grammar contains a base consisting of trees with associated terminal strings.

(2) The grammar contains T-rules which map trees onto trees. In particular, they apply to trees of the base to yield structures to which further T-rules can apply, etc.

(3) Each T-rule is specified by a domain statement and a structural change statement.

In the next section, we shall formalize the definition of a T-grammar on the basis of the above three properties. We shall also incorporate some properties not exemplified in the sample grammar. For example, the ordering of the T-rules and the definition of the languages generated are concepts which require specification.

2. FORMALIZATION

In this section we present a mathematical model of T-grammars. In particular, we shall define T-rules, the operation of T-rules, the order in which the T-rules may be applied (i.e., the "traffic rules"), and the language generated by the grammar.
A. Base

As was mentioned in the preceding section, T-grammars are commonly said to have a set of CF or CS rules that generate trees to which T-rules apply. In actual practice, special orders are imposed on the use of these rules (Peters, 1966), so that their usage differs from that given in either CF or CS grammars. Since our interest in this paper is in the T-rules and not the schemes used for deriving an original set of trees, we shall ignore such schemes and assume the existence of a given set of trees, called a "base." 12

In order to discuss "bases," we first consider "finite trees with labeled nodes," henceforth abbreviated "trees." We assume each non-empty tree has a "root." 13 Following the convention in the linguistic literature, we draw trees with the root at the top. We also need

Agreement. All trees in this paper are assumed to have the property that if a node has exactly one node immediately below it, then the two nodes have different labels. Each tree not of this form is to be automatically identified with the tree obtained by identifying such pairs of nodes in the obvious manner.

As an example, the tree in Fig. 1 is automatically considered to be the tree in Fig. 2.

The agreement is included because the T-rules as defined in our model cannot distinguish between such identified configurations. The condition is linguistically reasonable (and its equivalent has always been included in linguistic definitions of CF and CS grammars). It may be regarded as a special case of tree pruning. (See Ross (1965; 1967, Chapter 3) and Section 3, Example 6, below.)

We now briefly describe a base and the type of trees in it.

Definition. A base $\mathfrak{B}$ is a triple $(B, V, \Sigma)$, where $V$ is a finite non-empty set, $\Sigma$ (the set of terminal symbols) is a subset of $V$, and $B$ is a set of non-empty trees, each of which (i) has its terminal nodes labeled with symbols of $\Sigma$ (so that terminal nodes are labeled with terminals 14) and (ii) has its nonterminal nodes labeled with symbols of $V - \Sigma$.

12 A suggestion for specifying the set of base trees by a means other than CF or CS rules appears in McCawley (1968).

13 We assume the reader is familiar with the concept of a finite tree with labeled nodes and a root.

14 For some purposes it might be desirable to allow terminal nodes to be labeled with symbols of $\Sigma \cup \{\epsilon\}$, but for the purposes of this paper there is no need to do so.
DEFINITION. The associated word or the terminal string of a tree $\tau$ satisfying (i) and (ii) above, whether or not in $B$, is the word formed by concatenating the labels of the terminal nodes of $\tau$ in the usual left-to-right order.

B. Transformation Rules

As already noted, a T-rule is a rule which transforms trees into other trees. It has two parts: a “domain statement” and a “structural change statement.” In this subsection we shall formally define T-rules, and in the next subsection we shall specify how they operate on trees.

Notation. Given $\mathfrak{g} = (B, V, \Sigma)$, let $\Sigma'$ denote a finite superset of $\Sigma$ such that $\Sigma'$ and $V - \Sigma$ are disjoint. Let $X$ denote a new symbol (a “dummy variable”) and let $V' = V \cup \Sigma' \cup \{X\}$. Let $V''$ denote a set consisting of $V'$ plus a finite number of new symbols of the form $Y^{(i)}$, where $Y$ is in $V'$ and $i$ is a nonnegative integer.

We now define the notion of a “domain statement.”

DEFINITION. A Boolean domain statement is any expression formed as follows:

(1) Each string $\alpha_1 \cdots \alpha_k$, $k \geq 1$, every $\alpha_i$ in $V''$, is a Boolean domain statement.

(2) If $D_1$ and $D_2$ are Boolean domain statements, then $(D_1 \lor D_2)$, $(D_1 \land D_2)$, and $\neg D_1$ are Boolean domain statements.

We shall omit parentheses whenever no ambiguity results.

DEFINITION. A domain statement is any expression of the form $D_I$ or $D_I \land D_o$, where $D_I$ is a string $\alpha_1 \cdots \alpha_k$, $k \geq 1$, every $\alpha_i$ in $V''$, and $D_o$ is a Boolean domain statement.
A typical domain statement is written as either \( D, D = D_I, \) or \( D = D_I \land D_O, \) with \( D_I \) and \( D_O \) as above.

We now define the notion of a "structural change statement."

**Definition.** Let \( D = D_I \) or \( D = D_I \land D_O \) be a domain statement, with \( D_I = \alpha_1 \cdots \alpha_n \). A structural change statement (on \( D \)) is a string \( C = \beta_1 \cdots \beta_n \) such that for each \( i \), (i) is a new symbol, \( \beta_i = \text{if } i \text{ is in } H, \) and \( \beta_i \) is in \((\mathcal{Z}' \cup \{\emptyset, \{\}, \ldots, \{\alpha\}\}) - H)\) if \( i \) is not in \( H \), where \( H = \{j/\alpha_i \in \{X, X^{(1)}, \ldots \} \} \).

It will be subsequently seen that the above conditions on \( H \) guarantee that a T-rule cannot alter or move any parts of the tree that are designated by one of the variables \( X, X^{(1)}, \ldots \) etc. The manner in which the structural change statement produces new constituent structure from old is specified in the next subsection.

Note that whereas \( D = D_I \) or \( D = D_I \land D_O \), \( C \) is defined only with respect to \( D_I \). Intuitively described, the role of \( D_O \) is only to add further conditions, beyond those specified in \( D_I \), which a tree must satisfy in order for the T-rule to be applicable to it. (See Section C below.) The role of \( D_I \) is both to impose conditions which must be satisfied by a tree and to define the structure on which the changes specified by \( C \) will operate.

We are now able to formally define a T-rule.

**Definition.** A transformation rule \( T \) is an ordered pair \((D, C)\), where \( D \) is a domain statement and \( C \) is a structural change statement on \( D \).

We illustrate the concept of a T-rule by examining \( T_{pas} \) and \( T_{rel} \).

**Example.** Consider \( T_{pas} \). The domain statement is \( D_I \), where \( D_I = \alpha_1 \cdots \alpha_8 = X^{(1)}N_p(1)T_mV_bN_p(2)\). The structural-change statement is \( \beta_1 \cdots \beta_8 = \{1-2-3-4 \} \) be \( E_6 \) by \{5-7-8\}.

**Example.** Consider \( T_{rel} \). A first thought is that the domain statement is \( D_I \), where \( D_I = \alpha_1 \cdots \alpha_9 = X^{(1)}N_a(1)\) the \( N_a(1)X^{(2)} \) \( N_a(1)X^{(3)} \). However, this does not provide for the restriction that \( \alpha_6 \alpha_8 \) must be generated by \( N_p \). The solution is to have the condition that \( \alpha_6 \alpha_8 \) is generated by \( N_p \) expressed in a Boolean domain statement. In particular, the domain

\footnote{For each set \( E, E^+ \) is the set of all non-empty strings of elements from \( E \) and \( E^* = E^+ \cup \{\epsilon\}. \)}

\footnote{The dash symbol, -1, is used to separate the \( \beta_i \). Thus, for example, \( \beta_1 = \{0\} \) and \( \beta_2 = \{3\} \) be \( E_6 \).}
statement is \( D_I \land D_o \), where

\[
D_I = \alpha_1 \cdots \alpha_9 = X^{(1)}N^{(1)}aX^{(2)}N^{(2)}aX^{(3)}aX^{(4)},
\]

and \( D_o = \alpha_{10} \cdots \alpha_{17} = X^{(1)}N^{(1)}aX^{(2)}N^{(2)}aX^{(3)}aX^{(4)}. \)

We shall see in C below how the new domain statement requires \( \alpha_9 \alpha_8 \) to be generated by \( N_p \). The structural change statement is \( \beta_1 \cdots \beta_9 = \odot \) that \( \odot \) that \( \odot \) that \( \odot \) that \( \odot \) that \( \odot \) that \( \odot \) that \( \odot \).

C. USE OF T-RULES

We now turn to the problem of how to apply a T-rule. Hereafter, each tree mentioned is assumed to (i) have its terminal nodes labeled with symbols of \( \Sigma' \), and (ii) have its nonterminal nodes labeled with symbols of \( V - \Sigma' \). We shall see that a T-rule is applied to certain trees to yield other trees. In particular, a T-rule may be applied to a given tree \( \tau \) if \( \tau \) "satisfies" the domain statement of the T-rule in a manner defined below.

**Definition.** A graph-assignment \( f \) is a function over \( V'' \) defined as follows:

(i) For \( \xi = \gamma \) or \( \xi = \gamma^{(i)} \), \( \gamma \) in \( V' - \{X\} \), \( f(\xi) \) is a tree with root labeled \( \gamma \).

(ii) For each \( \xi \) in \( \{X, X^{(1)}, X^{(2)}, \ldots\} \), \( f(\xi) \) is an arbitrary concatenation of (possibly null) trees.

**Definition.** (1) A tree \( \tau \) satisfies a string \( \alpha_1 \cdots \alpha_k \) for a graph-assignment \( f \) if \( f(\alpha_1) \cdots f(\alpha_k) \) is a cofinal residual proper subgraph of \( \tau \).

(2) A tree \( \tau \) satisfies a conjunction \( D_1 \land \cdots \land D_p \land \sim D_{p+1} \land \cdots \sim D_{p+m}(p, m \geq 0, \text{each } D_i \text{ a string}) \), if there exists a graph assignment \( f \) such that \( \tau \) satisfies each \( D_i, 1 \leq i \leq p \), for \( f \), and there exists no graph assignment \( f_1 \) such that \( (\alpha)\tau \) satisfies each \( D_i, 1 \leq i \leq p \), for \( f_1 \) and \( (\beta)\tau \) satisfies at least one \( D_{p+j}, 1 \leq j \leq m \), for \( f_1 \).

(3) A tree \( \tau \) satisfies a disjunction \( D_1 \lor \cdots \lor D_q, q \geq 1, \text{each } D_i \text{ a conjunction of form } (2) \text{ above, if } \tau \text{ satisfies at least one } D_i, 1 \leq i \leq q. \)

For a given tree \( \tau \) and a given string \( D \), there may be zero, one, or more than one graph assignment for which \( \tau \) satisfies \( D \).

\(^{17}\) Let \( \eta_1, \ldots, \eta_k \) be subgraphs of a tree. Then \( \eta_1 \cdots \eta_k \), the concatenation of the \( f(\alpha_i) \), is the graph obtained by placing the \( \eta_i \) next to each other in the order given, taking the nodes of the \( \eta_i \) as pairwise disjoint.

\(^{18}\) A subgraph \( \tau_1 \) of a tree \( \tau_2 \) is cofinal residual, if (a) for each node \( \nu_2 \) in \( \tau_2 \) there is a node \( \nu_1 \) in \( \tau_1 \) which is either \( \nu_2 \) itself or below \( \nu_2 \), and (b) if \( \nu_1 \) is a node of \( \tau_1 \) and \( \nu_2 \) is a node of \( \tau_2 \) below \( \nu_1 \), then \( \nu_2 \) is in \( \tau_1 \).

A subgraph of \( \tau_2 \) is proper if it is not \( \tau_2 \) itself.
The adjective "proper" in condition (1) rules out the root of any of the trees \( f(\alpha_i) \) being the root of the given tree \( r \). The necessity for having the root of no \( f(\alpha_i) \) be the root of the tree \( r \) arises in the description of the effect of a structural change, which could otherwise replace a tree with a sequence of trees having no common root.

We mention without proof that any two disjunctions of form (3) above, which are logically equivalent, are either both satisfied or both not satisfied for a given tree. Because of this, we shall say that a tree \( r \) satisfies a domain statement if \( r \) satisfies some equivalent domain statement of form (3) above.

**Example.** Let \( D = J^{(1)} X U J^{(1)} \). Let \( f_1 \) be the following function on \( V'' : f_1(J^{(1)}) \) is the tree in Fig. 3, \( f_1(U) \) is the tree in Fig. 4, \( f_1(X) \) is the structure in Fig. 5, and \( f_1 \) is irrelevant elsewhere. Let \( r_1, r_2, \) and \( r_3 \) be the trees in Figs. 6, 7, and 8, respectively.

Then \( r_1 \) satisfies \( D \) for \( f_1 \), \( r_2 \) does not satisfy \( D \) for \( f_1 \) (but does for some other graph assignment \( f \)), and \( r_3 \) does not satisfy \( D \) for any graph assignment \( f \).
EXAMPLE. Let \( \tau_1, \tau_2, \) and \( \tau_3 \) be as above. Let \( D = D_1 \land D_0 = J^{(1)}X J^{(2)} \land ((J^{(1)}X J^{(1)}) \land J^{(1)}E) \lor (JLE \land \sim JME)) \). Then \( \tau_2 \) and \( \tau_3 \) satisfy \( D \) but \( \tau_1 \) does not.

We are now ready to define how a T-rule changes a tree \( \tau \) into a tree \( \tau' \), written symbolically \( \tau \Rightarrow \tau' \) or \( \tau \Rightarrow' \).

Notation. Given a T-rule, \( T = (D, C) \), where \( D = D_1 \lor D_0 \), \( D_1 = \alpha_1 \cdots \alpha_n \), and \( C = \beta_1 \cdots \beta_m \), and given a graph assignment \( f \) for which \( \tau \) satisfies \( D \), let \( g_{r,f} \), abbreviated \( g \) when \( T \) and \( f \) are understood, be the function on \( (\{\emptyset, \{1\}, \cdots, \{m\}\} \cup \Sigma^+) \) defined as follows:

(i) \( g(\emptyset) = f(\emptyset) \), for \( \emptyset \) in \( \{1, \cdots, m\} \);
(ii) \( g(\{1\}) \) is the one-node tree with label \( \{1\} \), for \( \{1\} \) in \( \Sigma^+ \);
(iii) \( g(\emptyset) \) is the empty tree; and
(iv) \( g(\emptyset \cdots \emptyset, \{1\}, \cdots, \{m\}) = g(\{1\} \cdots g(\{m\})), \) for all \( \{1\}, \cdots, \{m\} \) in

\[ \{\emptyset, \{1\}, \cdots, \{m\}\} \cup \Sigma^+ \]  

Notation. Let \( T = (D, C) \) be a T-rule and \( \tau \) a tree which satisfies \( D \) for assignment \( f \). Let \( D = D_1 \lor D_0 \) or \( D = D_1 \land D_0 \), with \( D_1 = \alpha_1 \cdots \alpha_n \). Then \( f(\alpha_1) \cdots f(\alpha_n) \) is a cofinal residual subgraph of \( \tau \). Let \( \tau_0 \) be the structure formed from \( \tau \) by replacing, for each \( i \) such that \( \beta_i \neq \emptyset \), \( f(\alpha_i) \) with \( g(\beta_i) \) in the obvious manner. Write \( \tau \Rightarrow_T \tau' \) or \( \tau \Rightarrow' \), where \( \tau' \) is the largest tree (possibly the empty tree) contained in \( \tau_0 \).  

Clearly there always exists a unique such tree \( \tau' \) (for a given \( f \)).

To illustrate the relation of \( \tau' \) to \( \tau_0 \), if \( \tau_0 \) is the structure in Fig. 9 then \( \tau' \) is the tree in Fig. 10. Thus, \( \tau' \) need not coincide with \( \tau_0 \).

\[ \text{Fig. 7.} \]

\[ \text{Fig. 8.} \]

19 Recall that as used here, a tree must have each of its terminal nodes labeled with terminals. The structure \( \tau_0 \) need not have its terminal nodes labeled with terminals. (See Fig. 9.)
Examples. (a) $T_{pas}$ changes the tree in Fig. 7 of section one into the tree in Fig. 8 of Section 1.

(b) Let $T = (D, C)$, where $D = D_I, D_I = \alpha_1 \cdots \alpha_4 = J^{(1)} \cup J^{(1)}$ and $C = \beta_1 \cdots \beta_4 = \Theta^{(1)} \cdots \Theta^{(2)} \cup \emptyset - bb$. Let $f$ be defined (in part) by $f(J^{(1)})$ being the tree in Fig. 11, $f(X) = \emptyset$, and $f(U)$ being the tree in Fig. 12. The tree $r_2$ in Fig. 7 above satisfies $D$ for $f$. For the function $g_{r,f} = g, g(\beta_1) = g(\Theta^{(1)})$ is the structure in Fig. 13, $g(\beta_2)$ is $\emptyset$, $g(\beta_3)$ is $\emptyset$, and
\( g(\beta_4) = g(bb) \) is the sequence of trees \( b^* b \). Then \( \tau_2 \Rightarrow \tau' \), where \( \tau' \) is the tree in Fig. 14.

(c) Let \( T = (D, C) \), where \( D = D_I = \alpha_1 \alpha_2 \alpha_3 = LUX \), and \( C = \beta_1 \beta_2 \beta_3 = \emptyset - \ominus - \emptyset \). Then \( \tau \Rightarrow \tau' \), where \( \tau \) is in Fig. 15 and \( \tau' \) is in Fig. 16.

**D. Transformational Grammar**

We are now ready to formally define the concept of a T-grammar. In addition to the underlying base and the T-rules, the grammar will also have (i) a set \( \Sigma_A' \) of distinguished symbols over which the language generated by the grammar is defined, and (ii) a specification of the ordering of the T-rules. We shall discuss this last component after presenting the definition of the grammar.

**Definition.** A transformational grammar is a 4-tuple \( G = (\mathfrak{A}, \Delta, R, \Omega) \) satisfying the following conditions:

1. \( \mathfrak{A} = (B, V, \Sigma) \) is a base of trees.
2. \( \Delta = (\Sigma', \Sigma_A', X, V'') \), where
   a. \( \Sigma' \) is a finite set of abstract symbols such that \( \Sigma \subseteq \Sigma' \), and \( \Sigma' \) is disjoint from \( V - \Sigma \).
   b. \( X \) is an abstract symbol not in \( V \cup \Sigma' \).
   c. \( \Sigma_A' \subseteq \Sigma' \).
   d. \( V'' \) is a set containing \( V \cup \Sigma' \cup \{X\} \) plus a finite number of new symbols of the form \( Y^i \), where \( Y \) is in \( V \cup \Sigma' \cup \{X\} \), and \( i \) is a nonnegative integer.
3. \( R \) is a finite set of T-rules \( (D, C) \) with respect to \( V'' \), \( \Sigma' \), and \( X \).
4. \( \Omega = (K, \mathfrak{K}, \delta, s_0) \), where
   a. \( K \) is a finite set (of states) and \( s_0 \) (the start state) is in \( K \).
   b. \( \mathfrak{K} = \{N(s)/s \in K\} \), where each \( N(s) \) is a partially ordered set over \( R \cup \{stop\} \), stop being a special symbol occurring only as a maximal element. \(^{20}\)
   c. \( \delta \) is a mapping from a subset of \( K \times R \) into \( K \) (next state function).

The components \( \mathfrak{A}, \Delta, \) and \( R \) have already been discussed. (As noted above, \( \Sigma_A' \) is the set of symbols over which the language generated by the grammar is defined.) The component \( \Omega \) pertains to the order of application of the T-rules. In general, it is not true that a T-rule may be

\(^{20}\) Given a partially ordered set \( (Y, \leq) \), \( x \) is maximal (minimal) if, for \( y \) in \( Y \), \( y \leq x \) (\( y \geq x \)) implies \( y = x \). An element \( x \) is isolated if there is no \( y \neq x \) such that either \( x \leq y \) or \( y \leq x \).
applied any time its domain statement is satisfied. In fact, all T-grammars in the literature which we have seen have restrictions on the order of application of the T-rules. We now show how $\Omega$ effects restrictions on the use of the rules, and we shall see that the restrictions in the literature can be obtained by appropriate $\Omega$.

Informally, $K$ is a set of states which record the past history of the use of the rules. Call a T-rule, $T$, "applicable" to a given tree $r$ at state $s$ if (i) $r$ satisfies the domain statement of $T$, (ii) $T$ occurs in $N(s)$, and (ii) $T$ is not preceded in $N(s)$ by a T-rule whose domain statement $r$ satisfies. A "derivation" consists of either

(a) a sequence of T-rules $T_1, \ldots, T_k$, states $s_1, \ldots, s_{k+1}$, and trees $r_1, \ldots, r_{k+1}$ such that for each $i, 1 \leq i \leq k$, $T_i$ is applicable to $r_i$ at $s_i$, yielding $r_{i+1}$, and $s_{i+1} = \delta(s_i, T_i)$; or

(b) a sequence of T-rules $T_1, \ldots, T_{k-1}$, states $s_1, \ldots, s_k$, and trees $r_1, \ldots, r_k$ such that for each $i, 1 \leq i < k$, $T_i$ is applicable to $r_i$ at $s_i$, yielding $r_{i+1}$, $s_{i+1} = \delta(s_i, T_i)$, and STOP is in $N(s_k)$ and is not preceded by any T-rule applicable to $r_k$ at $s_k$.

We now make the preceding motions more precise.

Notation. Let $G = (A, \Delta, R, \Omega)$ be a T-grammar and $\rightarrow$ the relation between pairs $(r, s)$, where $r$ is a tree and $s$ is in $K$, defined as follows: Write $(r, s) \rightarrow (r', s')$ if there exists some $T$ in $R$ such that

($i$) $T \rightarrow T'$,
($i$) $T$ occurs in $N(s)$,
($i$) there is no $T'$ in $N(s)$ and $T < T'$, such that $r \rightarrow^* r'$.

Using the above notation, we now define the "language generated by a T-grammar."

Definition. A word $w$ is said to be generated by a T-grammar $G = (A, \Delta, R, \Omega)$, where $A = (B, V, \Sigma)$, $\Delta = (\Sigma', \Sigma_A', X, V'')$, and $\Omega = (K, \delta, \delta, s_0)$ if

(i) $w$ is in $(\Sigma_A')^*$, and
there exist \( r, r', \) and \( s' \) such that \( r \) is in \( B \), \( (r, s_0) \rightarrow^* (r', s') \rightarrow \text{STOP} \), and \( w \) is the terminal string of \( r' \).

The language generated by \( \mathcal{G} \), denoted by \( L(\mathcal{G}) \), is the set of all words generated by \( \mathcal{G} \).

The purpose of STOP and of the distinction between acceptable terminals \( (\Sigma^* \Sigma') \) and unacceptable terminals \( (\Sigma^* - \Sigma') \) is to eliminate from the language of a T-grammar, by methods akin to the methods in the linguistics literature, certain words generated by the rules of the grammar. The STOP symbol is primarily used to allow only certain words, derived at intermediate stages of words in the language, to also be in the language. The unacceptable terminals (cf. the use of \( \# \in [\text{Chomsky (1965)}] \)) are used primarily in those derivations which never lead to a word in the language. These uses are not mutually exclusive, however; i.e., each of these mechanisms may occasionally be used to perform the function of the other. In Section 4, we discuss some methods for reducing this “filter power.”

In passing, we mention that the model as defined, with CF base, generates all recursively enumerable sets. The analogous theorem, for a different model, is proved in Kimball (1967).

3. ORDERING AND GRAMMAR EXAMPLES

We now present some examples to illustrate the above notions. The first five give some indication of the variety and generality of the use of partially ordered sets to specify the order of rule applications. The sixth illustrates the operation of “tree-pruning.” The last one is a simple example of a T-grammar.

(1) The set of T-rules in virtually every T-grammar extant is linearly ordered, in part. The rules in a linearly ordered set of rules are divided into two types, “obligatory” and “optional.” An obligatory rule is one which must be applied if its domain statement is satisfied at the appropriate point in the derivation; an optional rule is one which need not be. (See, for example, Chomsky, 1957.) If \( R = \{T_1, \ldots, T_n\} \) is linearly ordered, in the order given, with \( T_{i_1}, \ldots, T_{i_2} \) optional, then the ordering system \( \Omega \) can be constructed as follows:

(i) \( K = \{s_0, \ldots, s_n\} \).
(ii) \( \delta(s_i, T_j) = s_j \), for all \( i, j \), \( 0 \leq i \leq n, 1 \leq j \leq n \).
(iii) In \( N(s_0) \), the obligatory rules are linearly ordered, with the last of them immediately preceding STOP. Each optional rule \( T_{i_j} \) is repre-
presented in \( N(s_0) \) as a maximal node, which is directly preceded by the last (in \( R \)) preceding obligatory rule, if there is one, and isolated if there is no preceding obligatory rule.

(iv) For all \( i, 1 \leq i \leq n, N(s_i) \) is formed from \( N(s_{i-1}) \) by removing \( T_i \).

To illustrate, let \( R = \{T_1, T_2, T_3, T_4, T_5\} \) be linearly ordered, in the order given, with \( T_1, T_2, \) and \( T_5 \) optional. Then \( \Omega \) is as follows: \( K = \{s_0, \ldots, s_5\} \) and \( \delta(s_i, T_j) = s_j \), for all \( i, j, 0 \leq i \leq 5 \) and \( 1 \leq j \leq 5 \), and \( N(s_0), \ldots, N(s_5) \) are in Fig. 1–Fig. 6, respectively.

(2) Recent versions of T-grammars, starting with Chomsky (1965), have assumed a cyclic order of application of T-rules. In this example, we ignore the linguistic problems involved in setting up the domain statement and simply show how a cyclic ordering is represented by our ordering scheme. If \( R = \{T_1, \ldots, T_n\} \) is cyclically ordered (i.e., the rules are applied in the order given, but starting over with \( T_1 \) after \( T_n \)), with each rule obligatory, and the derivation halts whenever there is no rule that can be applied, then \( \Omega \) is as follows:

- (i) \( K = \{s_0, \ldots, s_n\} \).
- (ii) \( \delta(s_i, T_j) = s_j \), for all \( i, j, 0 \leq i \leq n \) and \( 1 \leq j \leq n \).
- (iii) For all \( i, 1 \leq i \leq n, N(s_i) \) is in Fig. 7, and \( N(s_0) = N(s_n) \).

To illustrate, let \( R = \{T_1, T_2, T_3\} \). This cyclic ordering, with the rules obligatory, is represented as follows:

- (i) \( K = \{s_0, s_1, s_2, s_3\} \).
- (ii) \( \delta(s_i, T_j) = s_j \), for all \( i, j, 0 \leq i \leq 3, 1 \leq j \leq 3 \).
- (iii) \( N(s_0) = N(s_3) \) is in Fig. 8. The \( N(s_1) \) is in Fig. 9. The \( N(s_2) \) is in Fig. 10.

\[ \text{Fig. 1.} \quad \text{Fig. 2.} \quad \text{Fig. 3.} \]
\[ \text{Fig. 4.} \quad \text{Fig. 5.} \quad \text{Fig. 6.} \]
(3) In some grammars (e.g., Mitre Corp., 1964) the rules are cyclically ordered, except that certain rules are optionally and others obligatorily reapplied as often as possible before going to the next rule. (Such provisions are implicit in many grammars which appear to be cyclically ordered.) Here K, δ, and N(s₀) are as in Example 2. If T₁ is obligatorily reapplied as often as possible before going to the next (in R) rule, then N(s₁) is in Fig. 11. If Tᵢ is optionally reapplied indefinitely before going to the next rule, then N(sᵢ) is as in Fig. 12.

To illustrate, let R = {T₁, T₂, T₃, T₄} be cyclically ordered, with all rules obligatory, with T₂ obligatorily reapplied as many times as possible before going to T₃, and with T₃ optionally reapplied indefinitely before going to T₄. Then K = {s₀, s₁, s₂, s₃, s₄}, δ(sᵢ, Tⱼ) = sⱼ for all i, j 0 ≤ i ≤ 4 and 1 ≤ j ≤ 4, N(s₀) = N(s₄) is in Fig. 13, N(s₁) = N(s₂) is in Fig. 14, and N(s₃) is in Fig. 15.

(4) Recently the notion of an "anywhere" rule has been proposed (Ross, 1967). Roughly described, an "anywhere" rule is one which must (or may) be applied whenever its domain statement is satisfied. We consider only the case where R = {T₁, · · ·, Tₙ, T₄}, with T₁ to Tₙ obliga-
tory and cyclically ordered, and $T_A$ an obligatory anywhere rule. (We assume that $T_A$ is a reapplicable rule as in the preceding example; variations such as nonreapplicable anywhere rules, more than one anywhere rule, and optional anywhere rules, could all be represented by fairly obvious modifications.) Then $K = \{s_0, \ldots, s_n\}$. The next state function plays a more significant role in this case; $\delta(s_i, T_j) = s_j$ for $i, j$ with $0 \leq i \leq n, 1 \leq j \leq n$, and $\delta(s_i, T_A) = s_i$ for all $i, 0 \leq i \leq n$. The sets $N(s_i)$ are as in the cyclic case except that $T_A$ is added to each set as a zero element.\(^2\)

For example, let $R = \{T_1, T_2, T_3, T_A\}$, with $T_1$ to $T_3$ obligatory and cyclic, and $T_A$ an obligatory anywhere rule. Then $K = \{s_0, s_1, s_2, s_3\}$, $\delta(s_i, T_j) = s_j$ for all $i$ and all $T_j$ except $T_A$, and $\delta(s_i, T_A) = s_i$ for all

\(^2\) Given a partially ordered set $(X, \leq)$, $x$ is a zero element if $x \leq y$ for all $y$. 
$i, N(s_0) = N(s_1)$ is in Fig. 16, $N(s_1)$ is in Fig. 17, and $N(s_2)$ is in Fig. 18. 

(5) The stop symbol can be used in several ways to filter words from the language. The previous examples have illustrated its use in preventing words which occur in intermediate stages of certain derivations from being in the language. As another instance of its use, suppose a certain partially ordered set $N(s)$ contains no occurrence of stop. Then any tree $\tau$ occurring at state $s$ to which no rule in $N(s)$ can be applied is eliminated, since $(\tau, s) \not\rightarrow \text{stop}$ is false and there is no $\tau', s'$ such that $(\tau, s) \rightarrow (\tau', s')$. (For more drastic filtering, $N(s)$ may be empty for some states $s$.)

To illustrate the implications of the absence of stop, let $R = \{T_1, T_2, T_3\}$ be linearly ordered, let $K = \{s_0, s_1, s_2, s_3\}$, let $\delta(s_i, T_j) = s_j$ for all $i, j$, $0 \leq i \leq 3, 1 \leq j \leq 3$, and let $N(s_0)$ be as in Fig. 19, $N(s_1)$ as in Fig. 20, $N(s_2)$ as in Fig. 21, and $N(s_3)$ as in Fig. 22. Then any tree to which $T_3$ fails to apply as the last rule in the derivation is eliminated.
We now present a simple example of "tree-pruning" (Ross, 1967; 1967, Chp. 3), and [R2, Chapter 3].

Suppose that the trees in Figs. 23 and 24 arise as subtrees in derivations. Furthermore, suppose we want to (a) "prune" the S-node in Fig. 23, i.e., to delete the S-node without deleting the subtree under it, thereby obtaining the tree in Fig. 24, and (b) leave unchanged the tree in Fig. 25. This cannot be accomplished by one application of a T-rule for the following two reasons:

(i) The domain statement \( D = D_I \land D_o = \alpha_1\alpha_2\alpha_3 \land \alpha_4\alpha_5\alpha_6 = X^{(1)}N_pX^{(2)} \land X^{(1)}SX^{(2)} \) is satisfied by the trees in both Fig. 23 and Fig. 25.

(ii) Even if the trees in Fig. 23 and Fig. 25 could be distinguished by some domain statement, there is no way to substitute the N_p-subtree for the S-subtree (for both subtrees cannot be included in one \( D_I \), and only subtrees mentioned in \( D_I \) are affected by the structural change.)

The problem can be resolved by using the following sequence of T-rules, which are obligatory and linearly ordered with respect to each other. (We ignore here the question of how they might relate to the other rules of a grammar):

\[
T_1 = (D, C), \text{ where } D = D_I \land D_o = \alpha_1\alpha_2\alpha_3 \land \alpha_4\alpha_5\alpha_6 = X^{(1)}SX^{(2)} \land X^{(1)}N_pX^{(3)} \land X^{(1)}NX^{(2)}, \text{ and } m \text{ is a new element of } \Sigma'. 
\]
\[
T_2 = (D, C), \text{ where } D = D_I \land D_o = \alpha_2\alpha_3\alpha_4 \land \alpha_6\alpha_7 = X^{(1)}N_pX^{(2)} \land X^{(1)}SX^{(2)} \land C = 1\rightarrow\emptyset \rightarrow 2\rightarrow 3. 
\]
\[
T_3 = (D, C), \text{ where } D = D_I = \alpha_1\alpha_3\alpha_6 = X^{(1)}mX^{(2)} \text{ and } C = 1\rightarrow\emptyset \rightarrow 3. 
\]

Then \( T_1 \) inserts the marker \( m \) adjacent to \( S \) in both Fig. 23 and Fig. 25, obtaining the trees in Fig. 26 and Fig. 27, respectively. \( T_2 \) applies only to the tree of Fig. 26, changing it to the tree in Fig. 24. \( T_3 \) removes the marker \( m \) from the tree of Fig. 27, restoring it to its original form (Fig. 25).
The above rules illustrate a type of procedure which can be used whenever two nodes, one below the other with no "branching" between, are both to be involved in a structural change. However, this technique does not allow one of two identically labeled nodes, one directly above the other, to be pruned. It was to avoid this situation that the agreement in Section 2A was made.

(7) For our last example, we present a T-grammar in its entirety. The grammar is $G = (B, \Delta, R, \Omega)$, where $\Delta, \Delta, R,$ and $\Omega$ are given below.

(a) $\Delta = (B, V, \Sigma)$, where

(i) $\Sigma = \{\$, P$_{set}$, the, eat, chase, dog, cat, mouse, recently, yesterday$\}.$

(ii) $V = \Sigma \cup \{S, S', N_p, A_{ux}, V_p, A_{dv}, V_b, N_n, T_{ns}\}.$

(iii) $B$ is the set of trees generated by the following set of CF rules, where $S$ is the start symbol:

\[
\begin{align*}
S & \rightarrow $S'$S' \\
S' & \rightarrow N_pA_{ux}V_p \\
S' & \rightarrow N_pA_{ux}V_pA_{dv} \\
V_p & \rightarrow V_bN_p \\
N_p & \rightarrow theN_n$S'\$ \\
N_p & \rightarrow theN_n \\
A_{ux} & \rightarrow T_{ns} \\
T_{ns} & \rightarrow P_{set}
\end{align*}
\]

\[
\begin{align*}
V_b & \rightarrow chase \\
V_b & \rightarrow eat \\
N_n & \rightarrow dog \\
N_n & \rightarrow cat \\
N_n & \rightarrow mouse \\
A_{dv} & \rightarrow recently \\
A_{dv} & \rightarrow yesterday
\end{align*}
\]
(b) \( \Delta = (\Sigma', \Sigma_d', X, V'') \), where

(i) \( \Sigma' = \Sigma \cup \{ \text{be}, \text{E}_n, \text{by}, \text{that}, \text{itself}, \# \} \)

(ii) \( \Sigma_d' = \Sigma' - \{ \# \} \)

(iii) \( V'' = V \cup \Sigma' \cup \{ X \} \cup \{ X^{(1)}, \ldots, X^{(19)}, N_p^{(3)}, N_p^{(2)} \} \)

(c) \( R = \{ T_{\text{pas}}, T_{\text{reflex}}, T_{\text{adv}}, T_{\text{rol}}, T_{\text{fin}}, T_{\text{bound}} \} \), where

(i) \( T_{\text{pas}} \) is the rule \((D, C)\), with \( D = D_I \land D_o \), where

\[
D_I = \alpha_1 \cdots \alpha_9 = X^{(1)} S N_p^{(3)} T_v n b N_p^{(2)} X^{(7)} S X^{(2)}
\]

\[
D_o = \alpha_{10} \cdots \alpha_{14} \land \sim \alpha_{15} \cdots \alpha_{21} \land \sim \alpha_{22} \cdots \alpha_{30} \land \sim \alpha_{31} \cdots \alpha_{39} = X^{(1)} S X^{(2)} \land \sim X^{(1)} S X^{(3)} \land \sim X^{(4)} S X^{(3)} \land \sim X^{(6)} S X^{(6)} S X^{(2)} \land \sim X^{(7)} S X^{(2)}
\]

and \( C = \beta_1 \cdots \beta_9 = 1 \cdots 3 \cdots 7 \cdots 9 \)

(ii) \( T_{\text{reflex}} \) is the rule \((D, C)\), with \( D = D_I \land D_o \), where

\[
D_I = \alpha_1 \cdots \alpha_3 = X^{(1)} S N_p^{(3)} A v n b N_p^{(2)} X^{(7)} S X^{(2)}
\]

and \( C = \beta_1 \cdots \beta_3 = 1 \cdots 3 \cdots 5 \cdots 7 \)

(iii) \( T_{\text{adv}} \) is the rule \((D, C)\), with \( D = D_I \land D_o \), where

\[
D_I = \alpha_1 \cdots \alpha_9 = X^{(1)} S N_p^{(3)} A_v X^{(2)}
\]

and \( C = \beta_1 \cdots \beta_9 = 1 \cdots 3 \cdots 5 \cdots 7 \)

(iv) \( T_{\text{rol}} \) is the rule \((D, C)\), with \( D = D_I \land D_o \), where

\[
D_I = \alpha_1 \cdots \alpha_9 = X^{(1)} S N_p^{(3)} X^{(7)} S X^{(2)}
\]

and \( C = \beta_1 \cdots \beta_9 = 1 \cdots 3 \cdots 7 \cdots 9 \)

(v) \( T_{\text{bound}} \) is the rule \((D, C)\), with \( D = D_I \land D_o \), where

\[
D_I = \alpha_1 \cdots \alpha_9 = X^{(1)} S X^{(3)} S X^{(2)}
\]

and \( C = \beta_1 \cdots \beta_9 = 1 \cdots 3 \cdots 5 \)

(vi) \( T_{\text{fin}} \) is the rule \((D, C)\), with \( D = D_I \), where

\[
D_I = \alpha_1 \alpha_2 \alpha_3 = \# X \#
\]

All but the last conjunct of \( D_o \) are conditions designed to insure that the \( T \)-rule operate within the leftmost "lowest \( S' \) flanked by \$ markers" in the tree (see Footnote 23). Since these conditions will also be imposed on \( T_{\text{reflex}}, T_{\text{adv}}, T_{\text{rol}}, \), we shall abbreviate them as "LLS" (leftmost lowest \( S' \)). Thus, LLS is \( D_o \) above without \( \sim X^{(1)} S N_p^{(3)} T_v n b N_p^{(2)} X^{(7)} S X^{(2)} \). Since LLS requires 21 symbols to state, we shall assign it to \( \alpha_{1+i} \cdots \alpha_{i+21} \), where \( D_I = \alpha_1 \cdots \alpha_i \).

The last conjunct of \( D_o \), in combination with \( D_I \), asserts that the two noun phrases involved in the rule must be different.
and \( C = \beta_1 \delta_2 \delta_3 = \emptyset - \emptyset - \emptyset \)

(d) \( \Omega = (K, \mathcal{A}, \delta, s_{\text{bound}}) \), where \( K = \{ s_{\text{rel}}, s_{\text{pas}}, s_{\text{reflex}}, s_{\text{adv}}, s_{\text{bound}}, s_{\text{fin}} \} \), \( \mathcal{A} = \{ N(s_x)/s_x \text{ in } K \} \), with \( N(s_{\text{rel}}) \) as in Fig. 28, \( N(s_{\text{pas}}) \) in Fig. 29, \( N(s_{\text{reflex}}) \) in Fig. 30, \( N(s_{\text{adv}}) \) in Fig. 31, \( N(s_{\text{bound}}) \) in Fig. 32, \( N(s_{\text{fin}}) \) in Fig. 33, and \( \delta \) is defined by \( \delta(s_x, T_y) = s_y \) for all \( x \) and \( y \).

Note that this T-grammar includes all the rules of the example in Section 1 (with the T-rules expressed formally here) as well as several others. In addition, this T-grammar includes adverbs (i.e., "recently", and "yesterday"). The CF-rules introduce adverbs at the end of a sentence, as in "the cat ate the mouse yesterday." The T-rule \( T_{\text{adv}} \) moves adverbs to the beginning of the sentence, as in "yesterday the cat ate the mouse." The inclusion of \( T_{\text{reflex}} \) permits such sentences as "the mouse chased itself." \( T_{\text{bound}} \) converts the original boundary marker \$ to \# (at the end of each cycle). The provision that each rule apply within the leftmost lowest \( S' \), with \$ markers, combines (using the order of the rules) with the conversion of \$ to \#. The effect is that the subtrees headed by \( S' \) in the tree are operated on one at a time, from bottom to top (and left to right). At the end of the last cycle, \( T_{\text{fin}} \) deletes the outermost occurrence of \#, which is the "unacceptable terminal" (i.e., \( \Sigma' - \Sigma_{A'} = \{ \# \} \)).
The cat recently chased itself yesterday.
the cat past eat the mouse that recently past chase itself yesterday

FIG. 36.
The ordering of the rules consists essentially of a cycle on the linear sequence \( T_{rel}, T_{pas}, T_{reflex}, T_{adv}, \) and \( T_{bound} \), plus a \( T \)-rule \( T_{fin} \), which is the last to be applied. \( T_{pas} \) and \( T_{adv} \) are optional rules. \( T_{rel} \) is reappplicable (obligatorily).

We illustrate the operation of the \( T \)-grammar with the derivation of the sentence "the mouse that recently chased itself was eaten by the cat yesterday."

(i) The CF rules generate the tree \( \tau_0 \) given in Fig. 34.
(ii) \((\tau_0, s_{bound}) \vdash T_{reflex} (\tau_1, s_{reflex})\), where \( \tau_1 \) is the tree obtained by replacing the rightmost \( N_o \) in \( \tau_0 \) with the symbol "itself."
(iii) \((\tau_1, s_{reflex}) \vdash T_{adv} (\tau_2, s_{adv})\), where \( \tau_2 \) is in Fig. 35.
(iv) \((\tau_2, s_{adv}) \vdash T_{bound} (\tau_3, s_{bound})\), where \( \tau_3 \) is the tree obtained by replacing the two inner occurrences of \( S \) with \( # \).
(v) \((\tau_3, s_{bound}) \vdash T_{rel} (\tau_4, s_{rel})\), where \( \tau_4 \) is in Fig. 36.
(vi) \((\tau_4, s_{rel}) \vdash T_{pas} (\tau_5, s_{pas}) \vdash T_{bound} (\tau_6, s_{bound}) \vdash T_{fin} (\tau_7, s_{fin}) \vdash \text{STOP}\), where \( \tau_7 \) is in Fig. 37.

Since all the terminals of \( \tau_7 \) are in \( \Sigma_d' \), the resulting word is in the language generated by the \( T \)-grammar. As in the example of Section 1, we assume that morphophonemic rules not shown here convert the terminal string "the mouse that recently chase itself the cat yesterday" into "the mouse that recently chased itself was eaten by the cat yesterday."

4. RESTRICTIONS

The general model presented in Section 2 incorporates most of the important features of \( T \)-grammars described in the literature. However, linguists are trying to determine the narrowest possible class of grammars adequate for describing natural languages. In this section, we present a number of restrictions on the general model. These restrictions, taken in various combinations, provide submodels which correspond to conceptions of \( T \)-grammars already in the literature.

A \( T \)-grammar has been defined as a quadruple \( G = (\mathcal{B}, \Delta, R, \Omega) \), where \( \mathcal{B} \) is a base, \( \Delta \) specifies the vocabulary and its subparts, \( R \) is a set of \( T \)-rules, and \( \Omega \) is a specification of the order in which the \( T \)-rules can be applied. We therefore first list the various restrictions on \( \Delta \), then those on \( R \), and finally those on \( \Omega \).

\(^{22}\) See Footnote 2.
A. Restrictions on $\Delta$

Definition. $\mathcal{G}$ is terminal-preserving if $\Sigma' = \Sigma$, and in each rule $(D, C)$ in $R$, each $\beta_i$ is in $\{\emptyset, 0, 1, \cdots, \odot\}^+$. In other words, a terminal-preserving grammar is one in which no T-rule can introduce a new terminal. This restriction is an extreme version of the notion that the trees of the base should contain all the semantically relevant material (Katz and Postal, 1964).

Definition. $\mathcal{G}$ is terminal-blocking if $\Sigma'_A \neq \Sigma'$, i.e., if some of the terminals are unacceptable. $\mathcal{G}$ is $\alpha$-blocking if $\alpha_i \neq \alpha_i - \{\alpha\}$.

In Chomsky (1965), p. 138, the “boundary symbol” $\#$ appears to be the only unacceptable terminal.

B. Restrictions on $R$

Definition. $\mathcal{G}$ has weakly recoverable deletions (Katz and Postal, 1964, p. 80) if, for each T-rule $(D, C)$ and each $i, \beta_i$ in $C$, at least one of the following holds:

(a) for some $\beta_j$ in $C$, $\beta_j = u \odot v, u$ and $v$ in $(\Sigma' \cup \{\emptyset, 0, 1, \cdots, \odot\})$.

(b) $\alpha_i = \alpha_k$ for some $k \neq i$, and for some $\beta_j$ in $C$, $\beta_j = u \odot v, u$ and $v$ in $(\Sigma' \cup \{\emptyset, 0, 1, \cdots, \odot\})^+$.

(c) $\alpha_i$ is in $\Sigma'$.

$\mathcal{G}$ having weakly recoverable deletions requires each $\alpha_i$ whose index does not appear in the structural change statement to be either a terminal symbol (condition (c)), or identical to some $\alpha_k$ whose index appears in the structural change statement (condition (b)). Its effect is that given a tree and the T-rule applied to produce it, the preceding tree is determined to within a finite set of trees.

Definition. $\mathcal{G}$ has strongly recoverable deletions if for each T-rule and each $\beta_i$ in $C$, either condition (a) or condition (b) in the previous definition holds.

This property, in slightly different form, is suggested in Chomsky (1965; p. 145, p. 222, fn 1; p. 225, fn 13). Chomsky suggests that in the general theory there be a requirement that deletion be effected only by identical structures, and that such a requirement would eliminate the need for quantifiers in domain statements. (In our model, quantifiers are implicit in the use of identical superscripts such as $N_p^{(2)}$, $N_r^{(2)}$ etc.)

C. Restrictions on $\Omega$

Definition. $\mathcal{G}$ is naturally ordered if $R = \{T_1, \cdots, T_n\}$, $K = \{s_0, \cdots, s_n\}$, and $\delta(s_i, T_j) = s_j$ for all $i, j, 0 \leq i \leq n, 1 \leq j \leq n$. 

Although ordering of T-rules is often not explicitly described, most of the literature implicitly conforms to the requirement of natural ordering. An exception is the "anywhere rule," given in Example 4 of Section 3. Note that $\mathcal{G}$ being naturally ordered imposes no restriction on the $N(s_i)$.

Among the natural orderings, we now describe two important subcases, the "linearly ordered" and the "cyclically ordered."

**Definition.** $\mathcal{G}$ is **linearly ordered** if $R = \{T_1, \ldots, T_n\}$ is naturally ordered and for each $i$, $1 \leq i \leq n$,

(i) $T_i$ is a minimal element of $N(s_{i-1})$,

(ii) $N(s_i)$ is formed by removing $T_i$ from $N(s_{i-1})$, and

(iii) $\text{STOP}$ is a maximal element of $N(s_0)$ (and thus of each $N(s_i)$).

Note that optional and obligatory rules, as described in Example 1 of section three, may appear in a linearly ordered $T$-grammar.

**Definition.** $\mathcal{G}$ is **cyclically ordered** if, for $R = \{T_1, \ldots, T_n\}$, $\mathcal{G}$ has the following properties:

(i) $\mathcal{G}$ is naturally ordered.

(ii) $N(s_0) = N(s_n)$ and satisfies the following: the obligatory rules $T_{i_1}, \ldots, T_{i_k}$ of $R$ are simply ordered, i.e., $T_{i_j} < T_{i_{j+1}}$ for each $i < k$, and each precedes $\text{STOP}$. For each optional rule $T_i$, $T_{i_j} < T_i$ if $i_j < i$.

(iii) For all $i$, $1 \leq i \leq n$, $N(s_{i-1})$ contains $T_i$ as a minimal element.

(iv) Suppose $T_i$ is an isolated node in $N(s_{i-1})$. Then $T_i$ and $\text{STOP}$ are incomparable in $N(s_i)$. Furthermore, for each $j$, if $T_j < \text{STOP}$ in $N(s_{i-1})$ then $T_j < T_i$ and $T_j < \text{STOP}$ in $N(s_j)$.

(v) Suppose $T_i$ is not an isolated node in $N(s_{i-1})$. Then $T_i < \text{STOP}$ in $N(s_i)$. Furthermore, for each $j$, if $T_j < \text{STOP}$ in $N(s_{i-1})$ then $T_j < T_i$ in $N(s_i)$.

See Chomsky (1965) p. 134–138 for a linguistic discussion and a somewhat different formulation.\(^{23}\)

**Definition.** $\mathcal{G}$ is **unordered** if $R = \{T_1, \ldots, T_n\}$, $K = \{s_0\}$, $\delta(s_0, T_j) = s_0$, for all $j$, and in $N(s_0)$, for each $i$ either $T_i$ is an isolated node or $T_i$ precedes $\text{STOP}$. (That is, optional rules are isolated, while obligatory rules precede $\text{STOP}$.)

\(^{23}\) A typical rule of a cyclic grammar in the literature might have a domain statement which appears as $\# JL \#$. Since our model does not incorporate the notion of a "lowest sentence," such a domain statement would be restated in our system as $D_I \land D_O$, where $D_I = X^{(1)} \# JL \# X^{(0)}$, and $D_O$ is similar to the $LLS$ statement of Example 6 of Section 3.
To our knowledge an unordered T-grammar has not actually appeared in the literature, but its possibility has been suggested in informal discussions, frequently under the name "intrinsically ordered."

The final two definitions concern the use of ordering to accomplish blocking as illustrated in Example 5 of Section 3.

**Definition.** $\mathcal{G}$ is *order-blocking* if for at least one $s$ in $K$, $N(s)$ does not contain STOP as an isolated node.

Thus, a T-grammar is order-blocking if it does not permit free choice of STOP at every stage in every derivation. Such a grammar uses the ordering to prevent certain words which arise in intermediate stages from being in the language. This application of ordering is implicit in most generative grammars.

**Definition.** $\mathcal{G}$ is *nonblocking* if $\mathcal{G}$ is neither terminal-blocking nor order-blocking.

Thus $\mathcal{G}$ is nonblocking if every word which arises in a derivation is a word in the language. This notion is a slight extension of the notion of "nonblocking" as used in Klima.
