ABSTRACT

INTRODUCTION: Takotsubo cardiomyopathy is an apical ballooning syndrome, which can be triggered by stress. Only few case reports describe the onset of Takotsubo as a complication of neurosurgery procedures.

CLINICAL PRESENTATION: A case of a 53 year-old female with a spinal neurinoma and surgery-associated Takotsubo cardiomyopathy is demonstrated. The patient developed typical signs of a myocardial infarction with circulation depression and ST elevation, but normal cardiac enzymes at the end of surgery. Cardiac catheterization and levocardiography confirmed the absence of any critical coronary disease but the presence of a typical apical ballooning and midventricular hypokinesis. The patient recovered completely under supportive conservative and cardiological therapy, showing regular left ventricular pump function.

CONCLUSION: Interventions in neurosurgery and perioperative care should be kept as stress free as possible. Due to the possibility of neurogenic mechanisms related to cardiomyopathy, Takotsubo cardiomyopathy as an entity of stress-induced complications should be taken into consideration.

1. Introduction

Takotsubo cardiomyopathy is an entity of non-ischemic cardiomyopathy in which there is a sudden but temporary weakening of the myocardium.1 The clinical presentation of Takotsubo is similar to that of an acute myocardial infarction.2 Symptoms are acute substernal chest pain, dyspnea, syncope, shock, or electrocardiographic abnormalities. In contrast to these clinically impressive symptoms, further diagnostics cannot confirm a coronary syndrome with the signs of coronary occlusion and ischemic lesions. The onset of Takotsubo can be triggered by emotional stress or constant anxiety and unexpected catastrophic conditions.2,3

2. Case report

A 53 year-old woman was admitted to neurosurgery because of emerging gait disturbances and unspecific pain in the region of the lumbosacral spinal column. Clinical examination confirmed a spinal ataxia and pain radiating over the lower spine. Spine MRI visualized a space-occupying extradural lesion on the level of the ninth thoracic vertebra, suspected of being a typical neurinoma lesion, confirming an indication for surgical removal. Prior to admission the patient received no oral medications such as digitalis, ACE inhibitors, angiotensin-II receptor antagonists, or β-blockers and offered 12-channel-ECG without abnormalities.

After anesthesiological and clinical preparation including tibialis somatosensory and motor evoked potentials without pathological, surgery was carried out. The patient was lying in a prone position with constant monitoring under general anesthesia by means of propofol and sufentanil. Following fluoroscopy and skin incision, the Th9 lamina was explored and removed under intermittent ultrasound confirming the correct intraoperative positioning. The neurinoma was visualized and removed microsurgically. Shortly before completion, sudden circulation depression (84/60 mmHg) and blood gas analysis disturbances were observed (endexpiratory pCO2 24 mmHg, capillary pO2 pressure 84%). The intraoperative ECG showed acute ST elevations (Fig. 1), as typically associated with acute myocardial infarction. Due to pump-failure related hypotension, medication was adapted as follows: noradrenaline at 0.12 μg/kg/min and dobutamine at 2 μg/kg/min via feeding pump, adrenaline in fractions of 1.8 mg
The intraoperative ECG showed acute myocardial infarction like changes and ST segment elevations in the I–III, aVR and the V3 to V6 leads.

Echocardiography showed characteristic kinetic disturbances in the apical heart region.

and cafedrin–theodrenaline in 80 mg boluses. Acetylsalicylic acid (500 mg) was administered for the suspected diagnosis. Sufentanil (0.2 μg/kg/h), propofol (6 mg/kg/h) and midazolam (5 mg boluses) were continuously administered via feeding pump until the surgery was finished. Cardiac enzymes, including CK and CK-MB, remained at normal levels at all times. In cardiac angiography, no critical coronary disease was observed, but the presence of a typical apical ballooning and midventricular hypokinesis (Fig. 2). The following levocardiography showed the typical octopus pot configuration of the heart (Fig. 3). After diagnosing the Takotsubo cardiomyopathy, therapy was adapted symptomatically upon the patient’s overall clinical condition. Metoprolol (47.5 mg twice daily) and ramipril (5 mg once daily) were administered to prevent volume overload and to exclude further events. Anticoagulation therapy was stated with nadroparine for the first three days due to the risk of a left ventricular thrombus. The administration of acetylsalicylic acid was stopped because of the absence of a coexisting coronary atherosclerosis.

The patient recovered completely within one week under conservative therapy and cardiological support. She was discharged with metoprolol and ramipril at the given dosages. Clinical and diagnostic controls in the follow-up confirmed a stable cardiac functionality. No further cardiac events recurred in the 4 years follow-up.

3. Discussion

The presented case describes the rare but impressive onset of Takotsubo in the context of spinal neurosurgery for the first time. Some authors found a coincidence of surgical interventions and the onset of Takotsubo. Artukoglu and coworkers describe a case of Takotsubo in the context of knee arthroscopy. Gologorsky
and Gologorsky present the case of a 43-year-old female that developed the signs of Takotsubo intraoperatively during lumbar interbody fusion. Takotsubo has also been described in patients undergoing radiofrequency ablation therapy of hepatic tumors or ophthalmic surgery. These cases support the theory that stressful events may trigger Takotsubo. A sudden surgical pain stimulus combined with insufficient analgesia are hypothesized to probably cause a catecholamine surge in Takotsubo. High circulating levels of catecholamines seem to cause catecholamine-induced microvascular spasms with subsequent myocardial dysfunction and stunning. Akashi et al. concluded a possible reflect activation of central neurogenic mechanisms similar to those evoked by subarachnoid hemorrhage. However, elevated blood catecholamine levels are not always present.

Takotsubo is characterized by ST segment elevations especially in the anterior precordial leads, deep T wave inversions or abnormal Q waves. Also normal ECG presentations were described. Clinical findings are heart failure, brady- or tachyarrhythmia, mitral regurgitation, cardiogenic shock and pulmonary edema. Paraclinical findings are mildly elevated cardiac biomarkers such as high-sensitivity troponin assays or CK levels. Levoventriculography displays the apical ballooning and immobility, justifying the Japanese name or octopus pot, which is characteristic for Takotsubo cardiomyopathy.

Patients who survive the acute episode typically recover to normal ventricular function within four weeks. The prognosis is determined by the acute complications of Takotsubo. Despite the severity of the acute illness, Takotsubo is a transient disorder manageable with supportive therapy. Conservative treatment with resolution of the physical or emotional stress usually results in rapid resolution of symptoms. There are no controlled data to define an optimal medical regimen, but it seems reasonable to treat these patients with standard medications for left ventricular systolic dysfunction. These include ACE inhibitors, β-blockers and diuretics to prevent volume overload. However, because the condition may recur, on-going adrenergic blockade with β-blockers is suggested. Consequently, Takotsubo is a transient disorder managed with the resolution of physical or emotional stress and supportive therapy. Due to the personal needs in case of elective neurosurgery and the possibility of neurogenic mechanisms in triggering of Takotsubo, surgical interventions and perioperative care should be realized under stress-free conditions as far as possible.

Conflict of interest

The authors report no conflict of interest concerning the materials or methods used in this study or findings specified in this paper. Consent was ratified from the patient for publishing this case report.
