On unique kinematics for the branching shells

W. Pietraszkiewicz, V. Konopińska

Abstract

We construct the unique two-dimensional (2D) kinematics which is work-conjugate to the exact, resultant local equilibrium conditions of the non-linear theory of branching shells. It is shown that the compatible shell displacements consist of the translation vector and rotation tensor fields defined on the regular parts of the shell base surface as well as independently on the singular surface curve modelling the shell branching. Discussing relations between limits of the translation vector and rotation tensor fields when approaching the singular curve, and analogous fields given only along the singular curve itself, several types of the junctions are described. Among them are the stiff, entirely simply connected and partly simply supported junction as well as the elastically and dissipatively deformable junction, and the non-local elastic junction. For each type of junction the explicit form of the principle of virtual work is derived.

1. Introduction

Already Reissner (1974, 1982) noticed that the 2D kinematic structure of the general theory of regular shells, which is uniquely induced by the exact, resultant local shell equilibrium equations, corresponds to that proposed by Cosserat and Cosserat (1909). Libai and Simmonds (1983, 1998) formulated the 2D kinematics for shells modelled by a non-material weighted surface of mass taken as the shell base surface during deformation process. When the base surface is taken to be a material surface arbitrary located in the shell-like body, the 2D shell kinematics was discussed by Makowski and Stumpf (1994), Chrósćielewski et al. (1997, 2004) and summarised in detail in the book by Chrósćielewski et al. (2004), where references to other papers are given. In the above works the 2D shell kinematics was uniquely established as the work-conjugate dual structure following from some 2D integral identity of the virtual work type. As a result, the unique 2D shell displacements are described by six fields: three components of the translation vector \( u \) and three independent parameters of the rotation tensor \( Q \) fields describing the gross deformation of the shell cross section.

In case of irregular shell structures, called also multi-shells, several special cases of 2D six-field shell kinematics were discussed by Makowski and Stumpf (1994), Chrósćielewski et al. (1997, 2004) and Pietraszkiewicz (2001). In those works it was assumed that the region of irregularity (branching, self-intersection, stiffening, technological junction, etc.) is small as compared with other dimensions of the shell base surface and its size can be disregarded. Such an assumption introduced an undefinable error into the resultant dynamic continuity conditions at the singular surface curves and points modelling the regions of irregularity. Konopińska and Pietraszkiewicz (2007) removed this inaccuracy and formulated the exact, resultant 2D equilibrium conditions for the general, non-linear six-field theory of branching and self-intersecting shells.

In this note by extending the results of Konopińska (2007) we construct the dual structure work-conjugate to the exact resultant equilibrium conditions derived by Konopińska and Pietraszkiewicz (2007). This structure represents the unique 2D kinematics on the irregular shell base surface \( M \) for the branching shell. We begin with the integral identity (9) in which initially arbitrary vector fields \( v \) and \( w \) are interpreted as the kinematically admissible virtual translations \( \delta u \) and rotations \( \delta \omega \) corresponding to the real deformation of the shell base surface. This allows us to introduce the 2D principle of virtual work (21) formulated on the irregular material base surface \( M \) which includes the stationary singular curve \( \Gamma \) modelling the region of shell branching. As a result, the shell displacements consist of two fields \( u, Q \) on \( M \setminus \Gamma \) and independent two fields \( u_1, Q_1 \) defined only along \( \Gamma \). Then we discuss relations between limits of the fields \( u, Q \) when approaching \( \Gamma \) and the fields \( u_1, Q_1 \) themselves. In this way several types of junctions at \( \Gamma \) can be described. Among them are the stiff, entirely simply connected, partly simply supported and partly deformable junctions. For each type of junction we characterize its specific kinematics and establish the appropriate form of the principle of virtual work.
2. Notation and local equilibrium conditions

A shell is a 3D thin solid body identified in a reference (undeformed) placement with a region \( B \) of the physical space \( \mathcal{E} \) having \( E \) as its 3D translation vector space. The position vector \( x = x - o \) of any point \( x \in \mathcal{E} \) relative to an origin \( o \in \mathcal{E} \) can be given by

\[
x(x, \xi) = x(x) + \xi x(x),
\]

where \( x(x) = x(x, 0) \) is the position vector of a point of some undeformed base surface \( M \), while \( \xi \) is the distance from \( M \) to \( x \) along the unit vector \( t \) not necessarily normal to \( M \).

The position vector \( y = \chi(x) = y - o \) relative to the same origin \( o \in \mathcal{E} \) of any shell point \( y \) in the deformed placement \( B = \chi(B) \) can always be represented by

\[
y(x, \xi) = y(x) + \xi y(x), \quad z(x, 0) = 0.
\]

where \( y = \chi(x) \) is the position vector of the deformed material base surface \( M = \chi(M) \), and \( \xi \) is a deviation of \( y \) from \( B \).

For the branching and self-intersecting shells Konopińska and Pietraszkiewicz (2007) worked out the through-the-thickness integration procedure leading to the exact, resultant local equilibrium conditions for any part \( \Pi \subset M \) which includes the singular surface curve \( \Gamma \) modelling the common junction of regular branches \( M_k \), \( k = 1, \ldots, n \), of \( M \), with \( n = 3 \) for the branching and \( n = 4 \) for the self-intersection.

In the referential description these resultant local equilibrium conditions consist of the equilibrium equations in \( \Pi \subset M, \Gamma \):

\[
\text{Div}_\Pi N = \text{f} = 0, \quad \text{Div}_\Pi M + \alpha(NF^T - FN^T) + c = \tilde{c} = 0;
\]

the static boundary conditions along that part \( \partial \Pi \subset \partial M \) where the resultant forces and couples are prescribed,

\[
n^\mathcal{E} - Nv = \bar{n} = 0, \quad m^\mathcal{E} - Mv = \bar{m} = 0;
\]

the static continuity conditions along \( \Gamma \subset \Pi \),

\[
[Nv] + f = F = 0, \quad [Mv] + c = \tilde{c} = 0;
\]

and the static boundary conditions

\[
n_i - n_i = \bar{n}_i = 0, \quad m_i - m_i + y_i \times n_i = \bar{m}_i = 0, \quad \text{at the singular points } x_i \in \Gamma \cap \partial M_i, \text{ see Fig. 1.}
\]

In (3)–(5), \( (N, M) \in E \otimes T_M \) are the surface stress resultant and stress couple tensors of the 1st Piola–Kirchhoff type, which are related to the corresponding stress resultant and stress couple vectors \( n, m \), defined along any edge \( \partial \Pi \) of a regular part \( \Pi \subset M \) by the surface Cauchy theorem \( n = Nv, m = Mv \), where \( v \in T_M \) is the unit vector externally normal to \( \partial \Pi \). In (3)–(6), \( (f, c) \in E \) are the surface resultant force and couple vectors, \( \text{Grad} \) and \( \text{Div} \) denote the referential surface gradient and divergence operators on \( M, (n^\mathcal{E}, m^\mathcal{E}) \in E \) are the boundary resultant force and couple vectors along \( \partial M \), \((f^\mathcal{E}, c^\mathcal{E}) \in E \) are the compensating curvilinear resultant force and couple vectors along \( \Gamma \), while \( n, m, n, m \) are the compensating concentrated force and couple vectors applied at the initial \( x_i \) and end \( x_f \) points of \( \Gamma \), respectively. Additionally, \( \alpha(A) \) means the axial vector of the skew tensor \( A^T - A \), \( (a) \) is the jump of the vector field \( a \) at the singular surface curve \( \Gamma \), and \((\cdot)^\mathcal{E} = \xi_E (\cdot) \).

In Konopińska and Pietraszkiewicz (2007) the compensating concentrated forces \( n, m \) and couples \( m, m \) were equivalently represented by curvilinear integrals over some distributed loads \( n, m \) along \( \Gamma \). In the present paper we do not use this equivalent representation.

The relations (3) and (4) are formally equivalent to those given for the regular shell for example by Libai and Simmonds (1983) and Makowski and Stumpf (1990). The static relations (5) and (6) complete by some correcting terms various analogous approximate relations proposed by Makowski and Stumpf (1994), Christiansen et al. (1997, 2004) and Pietraszkiewicz (2001) using alternative approximate reduction procedures.

To avoid ambiguity, let us recall that in this paper the surface gradient Grad, of a differentiable vector field \( \psi(x) \in E \) is the 2nd-order tensor field \( \text{Grad} \psi(x) \in E \otimes T_M \) defined by

\[
\{\text{Grad} \psi(x)\} a = \frac{d}{dt} (\psi(x + ta))|_{t=0} \quad \text{for any } t \in \mathbb{R}, \ a \in T_M, \quad t \in \mathbb{R}.
\]

The surface divergence Div\( s \) of a differentiable tensor field \( A(x) \in E \otimes T_M \) is the vector field \( \text{Div}_s A(x) \in E \) satisfying

\[
\{\text{Div}_s A(x)\} b = \text{Div}_s \{A^T(x) b\} = \text{tr} \{\text{Grad}_s (A^T(x) b)\} \quad \text{for any } b \in E.
\]

3. Work-conjugate shell kinematics

Let \( (v, w) \in E \) be two vector fields smooth in regular points of \( M, \Gamma \), and \( (v_f, w_f) \in E \) be two other vector fields smooth along \( \Gamma \) including the initial \( x_i \) and end \( x_f \) points of \( \Pi \cap \Gamma \). Then for any part \( \Pi \subset M \) containing a part of \( \Gamma \), Fig. 1, we can set the integral identity

\[
\int_{\Pi \cap \Gamma} (\bar{f} \cdot v + \bar{c} \cdot w) ds + \int_{\partial \Pi \cap \partial M} (\bar{n} \cdot v + \bar{m} \cdot w) ds - \int_{\partial \Pi \cap \partial M} (\bar{f} \cdot v_f + \bar{c} \cdot w_f) ds - \bar{n}_i \cdot v_f - \bar{m}_i \cdot w_f = 0.
\]

Introducing (3)–(6) into (9) we can transform the identity as suggested in Christiansen et al. (2004, Chapter 3).

In particular, note that by simple algebra

\[
(\text{Div}_s N) \cdot v = N \cdot \text{Grad} v, \quad (\text{Div}_s M) \cdot w = M \cdot \text{Grad} w, \quad \text{and} \quad \alpha(NF^T - FN^T) \cdot w = -\frac{1}{2} (NF^T - FN^T) \cdot w = N \cdot (WF),
\]

where \( \cdot \) is the scalar product in the tensor space such that for any \( A, B \in E \otimes T_M, A \cdot B = \text{tr}(A^T B) \), \( W = w \times 1 \) is the skew tensor, and \( 1 \) means the unit tensor of \( E \).
Let us apply in the reverse order the divergence theorem used by Konopińska and Pietszczukiewicz (2007, f. (23)–(26)). Then the first integral of (9) with (10) can be transformed as follows:

\[
\int_{M;\Gamma} (\mathbf{f} \cdot \mathbf{v} + \mathbf{c} \cdot \mathbf{w})d\mathbf{a} = \int_{M;\Gamma} (\text{Div}\mathbf{N} + \mathbf{f}) \cdot \mathbf{v} + \mathbf{c} \cdot \mathbf{w}d\mathbf{a} = -\int_{M;\Gamma} \{\mathbf{N} \ast \text{Grad}\mathbf{v} - \mathbf{N} \ast (\mathbf{WF})\} d\mathbf{a}
\]

\[= \int_{M;\Gamma} (\mathbf{M} \ast \text{Grad}\mathbf{w})d\mathbf{a} + \int_{M;\Gamma} \{\mathbf{Mv} \cdot \mathbf{w}\}d\mathbf{a} + \int_{M;\Gamma} (\mathbf{Nv} \cdot \mathbf{v} + \mathbf{Mv} \cdot \mathbf{w})d\mathbf{a} + \int_{\partial M;\Gamma} (\mathbf{Nv} \cdot \mathbf{v} + \mathbf{Mv} \cdot \mathbf{w})d\mathbf{s}.
\]

In (11), \(\partial M_d = \partial M \ast \partial M_f\) is the complementary part of \(\partial M\) where the kinematic boundary conditions \(u = u^\prime, Q = Q^\prime\) are prescribed, and the jumps along the singular curve \(\Gamma\) are defined by

\[
\{\mathbf{Nv} \cdot \mathbf{v}\} = \sum_{k=1}^{3} N_i v_k \cdot v_k, \quad \{\mathbf{Mv} \cdot \mathbf{w}\} = \sum_{k=1}^{3} M_k v_k \cdot w_k.
\]

In (12), \(N_k \) and \(M_k\) are the one-sided finite limits of \(N\) and \(M\) when the respective boundary \(\partial M_k\) coinciding with \(\Gamma\) is approached, respectively, and \(v_k \in T_M d\mathbf{a}\) is the unit vector externally normal to \(\partial M_k\).

The second integral of (9) can be divided into two parts

\[
\int_{\partial M;\Gamma} (\mathbf{n} \cdot \mathbf{v} + \mathbf{m} \cdot \mathbf{w})d\mathbf{s} = \int_{\partial M;\Gamma} (\mathbf{n}^\prime \cdot \mathbf{v} + \mathbf{m}^\prime \cdot \mathbf{w})d\mathbf{s} - \int_{\partial M;\Gamma} (\mathbf{Nv} \cdot \mathbf{v} + \mathbf{Mv} \cdot \mathbf{w})d\mathbf{s}.
\]

The third integral of (9) can also be rewritten in two parts

\[
-\int_{M;\Gamma} (\mathbf{f} \cdot \mathbf{v} + \mathbf{c} \cdot \mathbf{w})d\mathbf{a} = -\int_{M;\Gamma} (\mathbf{Nv} \cdot \mathbf{v} + \mathbf{Mv} \cdot \mathbf{w})d\mathbf{a} + \int_{\partial M;\Gamma} (\mathbf{f} \cdot \mathbf{v} + \mathbf{c} \cdot \mathbf{w})d\mathbf{s}.
\]

where all fields are defined only along \(\Gamma\).

Since \(H\) is an arbitrarily chosen part of \(M\), the results presented in (11)–(14) are valid for the whole \(M\) as well, so that (9) with (11), (13) and (14) for the whole \(M\) with \(\Gamma\) leads to

\[
-\int_{M;\Gamma} \{\mathbf{N} \ast (\text{Grad}\mathbf{v} - \mathbf{WF}) + \mathbf{M} \ast \text{Grad}\mathbf{w}\} d\mathbf{a} + \int_{M;\Gamma} (\mathbf{f} \cdot \mathbf{v} + \mathbf{c} \cdot \mathbf{w})d\mathbf{a} + \int_{\partial M;\Gamma} (\mathbf{n} \cdot \mathbf{v} + \mathbf{m} \cdot \mathbf{w})d\mathbf{s} = -\int_{M;\Gamma} (\mathbf{Nv} \cdot \mathbf{v} + \mathbf{Mv} \cdot \mathbf{w})d\mathbf{a} + \int_{\partial M;\Gamma} (\mathbf{Nv} \cdot \mathbf{v} + \mathbf{Mv} \cdot \mathbf{w})d\mathbf{s} + \int_{\partial M;\Gamma} (\mathbf{f} \cdot \mathbf{v} + \mathbf{c} \cdot \mathbf{w})d\mathbf{s}.
\]

Let the real shell deformation be described by the translation vectors \(u = y - x \in E\) and \(\mathbf{u}_r = y_r - x_r \in E\) of the base surface as well as the rotation tensors \(Q\) and \(\mathbf{Q}\) \(\subset O(3)\) of the shell cross sections defined as \(Q = d_\mathbf{f} \odot t, Q_r = d_\mathbf{f}_r \odot t_r\), where \(d_\mathbf{f}, d_\mathbf{f}_r\) and \(t, t_r\) = \((t_x, t, t)\), \(t_r^i, i = 1, 2, 3, \alpha = 1, 2\), are triads of orthonormal directors in the deformed and undeformed placement associated with \(M;\Gamma\) and \(\Gamma\), respectively. Then the vector fields \(v, \mathbf{v}_r, w, \mathbf{w}_r\) may be interpreted, in particular, as the kinematically admissible virtual translations and rotations

\[
\mathbf{v} = \delta \mathbf{u}, \quad \mathbf{v}_r = \delta \mathbf{u}_r, \quad \mathbf{w} = (\delta \mathbf{Q}) \mathbf{Q}_r^T \equiv \mathbf{w}_r = (\delta \mathbf{Q}) \mathbf{Q}_r^T \equiv \mathbf{w}_r, \quad (16)
\]

such that \(\delta \mathbf{u} = \mathbf{w} = 0\) along \(\partial M_d\), and \(\delta\) is the symbol of virtual change (variation). With such virtual displacements the integral over \(\partial M_d\) in the third row of (15) vanishes. In the last two rows of (15) the terms at points \((x, x) \in \partial M_d\) identically vanish as well, because the compensating concentrated forces and couples are defined only at \((x, x) \in \partial M_f\).

Moreover, two integrals in the second row, the first integral in the third row and terms in the last two rows of (15) may now be interpreted as the external virtual work performed by the given surface \(f, c\), boundary \(n^\prime, m^\prime\) and compensating concentrated \(n, n_r, m, m_r\) loads as well as by the compensating loads \(f_r, c_r\) prescribed along \(\Gamma\), respectively. In this context the first surface integral in (15) should have the meaning of internal virtual work performed by \(N, M\) on the respective virtual strain measures \(\text{Grad}\delta \mathbf{u} - \Omega \mathbf{F}\). Grad\(\mathbf{w}\), \(\Omega = \mathbf{w} \times 1\). These virtual strain measures should now be expressed by variations of appropriately defined global 2D stretch and bending tensors on \(M;\Gamma\).

The 2D strain measures on \(M;\Gamma\) corresponding to the 2D virtual strain measures were discussed in Chróścielewski et al. (2004), Pietszczukiewicz et al. (2005) and Eremeyev and Pietszczukiewicz (2006). It was found that

\[
\text{Grad}\delta \mathbf{u} - \Omega \mathbf{F} = \delta E, \quad \text{Grad}\mathbf{w} = \delta \mathbf{K},
\]

where \(\delta(\cdot) = \mathbf{Q}(\mathbf{Q}^\prime(\cdot))\) is the co-rotational variation of \((\cdot)\), and the 2D stretch and bending tensors are defined by

\[
E = \mathbf{F} - \mathbf{Q}^T, \quad \mathbf{K} = \mathbf{CF} - \mathbf{QB}.
\]

In (18), \(I = \text{Grad}\mathbf{x} \in E \otimes T_M\) and \(J = \text{grad} \mathbf{y} \in E \otimes T_M\) are the inclusion operators on \(M;\Gamma\) and \(\mathbb{M} \setminus T; F \in T_M \otimes T_M\) is the tangential surface deformation gradient such that \(d\mathbf{y} = d\mathbf{x}\), while \(B\) and \(C\) are the structure curvature tensors of the base surface in the undeformed \(\mathbb{M}\) and deformed \(\mathbb{M} \setminus T\) placements, respectively, defined as follows:

\[
\mathbf{T} = t_i \otimes \mathbf{e}_i, \quad \text{ax}(\mathbf{dT}T^{-1}) = B d\mathbf{x}, \quad \mathbf{B} \in E \otimes T_M,
\]

\[
\mathbf{D} = \mathbf{QT} = d_i \otimes \mathbf{e}_i, \quad \text{ax}(\mathbf{dD}D^{-1}) = C d\mathbf{y}, \quad \mathbf{C} \in E \otimes T_M,
\]

where \(e_i\) are the orthonormal base vectors of a 3D inertial frame of reference.

The description of shell deformation given in (16)–(19) is equivalent to that proposed by Cosserat and Cosserat (1909).

If we introduce the virtual strain energy density in \(M;\Gamma\) defined as

\[
\sigma = N \ast \delta E + M \ast \delta \mathbf{K},
\]

then the principle of virtual work following from (15) for the branching shell can be given in the form
\[ \iint_{M^k} \sigma da = \iint_{M^k} (f \cdot \delta u + c \cdot \omega) da \]
\[ + \int_{\partial M^k} (n^r \cdot \delta u + m^r \cdot \omega) ds \]
\[ - \int_{\partial M^k} (f^r \cdot \delta u + c^r \cdot \omega) ds \]
\[ + \int_M ([Nv \cdot \delta u] - [Nv] \cdot \delta u_r + [Mv \cdot \omega] - [Mv] \cdot \omega_r) ds \]
\[ - (n_r - \delta u_r - n_r - \delta u_r) \]
\[ - \{(m_r + y_c \times n_r) \cdot \omega_r - (m_r + y_c \times n_r) \cdot \omega_r\} \]  \( (21) \)

In the PVW (21), two surface integrals over \( M', \Gamma \) and one line integral along \( \partial M \) are the classical contributions appearing for the regular base surface. All other terms in (21) take into account that now \( M \) is the irregular surface containing the singular curve \( \Gamma \) modelling the surface branching. The minus sign in front of some terms reflects the virtual works of compensating loads which had to be subtracted in Konopinska and Pietraszkiewicz (2007) to assure the exact global force and couple equilibrium of the branching shell.

The line integral along \( \Gamma \) in the fourth and fifth rows of (21) contains the jump terms which explicit forms depend on the type of junction modelled by \( \Gamma \). This integral describing the shell-junction interaction (S-JI) for some types of shell junction will be discussed in detail below.

4. Junctions at shell branching

Let us discuss in more detail the branching shell whose undeformed base surface \( M \) consists of three regular parts \( M_k, k = 1, 2, 3 \), joined together along the common junction modelled by the singular curve \( \Gamma \), see Fig. 1.

In general, one can independently characterise the behaviour of all six components of \( u \) and \( Q \) when \( \Gamma \) is approached along a path within each \( M_k \). This would lead to a large variety of junctions characterised by any of \( 36 \) combinations of such relations for each \( M_k \).

In this paper we assume that the translations of the base surface always remain continuous during deformation, i.e. the kinematic continuity conditions \( u_k = u_r \) are always satisfied, where \( u_k \) mean the one-sided limits of \( u \) on each \( M_k \) when \( \Gamma \) is approached.

Since
\[ [Nv \cdot \delta u] = [Nv] \cdot \delta u \]
\[ + (Nv) \cdot \delta u_r \]  \( (22) \)
where \( (a) \) means the average value of \( a \) at \( \Gamma \), by translational continuity conditions we have \( (\delta u) = \delta u_r \) and \( \delta u = 0 \), so that in this case
\[ [Nv \cdot \delta u] = [Nv] \cdot \delta u_r \]  \( (23) \)

With (23), the first two terms in the S-JI integral of the fourth and fifth rows of (21) cancel each other out. As a result, different types of junctions along \( \Gamma \) can now be characterised by additional constraints put on one-sided limits \( Q_k \) of \( Q \) when \( \Gamma \) is approached.

4.1. Stiff junction

The junction is called stiff along \( \Gamma \) if both \( u \) and \( Q \) are continuous on the whole \( M \) including \( \Gamma \), see Fig. 2, that is
\[ u_k = u_r, \quad Q_k = Q_r, \quad k = 1, 2, 3. \]  \( (24) \)

In this case in the integrand of the S-JI integral we have not only (23) but also
\[ [Mv \cdot \omega] = [Mv] \cdot \omega_r, \]  \( (25) \)
so that the S-JI integral identically vanishes. As a result, the kinematics of the branching shell with all junctions stiff along \( \Gamma \) is entirely described by two fields \( u, Q \) smooth in the whole \( M \) containing \( \Gamma \). The corresponding PVW reads
\[ \iint_{M^k} \sigma da = \iint_{M^k} (f \cdot \delta u + c \cdot \omega) da \]
\[ + \int_{\partial M^k} (n^r \cdot \delta u + m^r \cdot \omega) ds \]
\[ - \int_{\partial M^k} (f^r \cdot \delta u + c^r \cdot \omega) ds \]
\[ + \int_M ([Nv \cdot \delta u] - [Nv] \cdot \delta u_r + [Mv \cdot \omega] - [Mv] \cdot \omega_r) ds \]
\[ - (n_r - \delta u_r - n_r - \delta u_r) \]
\[ - \{(m_r + y_c \times n_r) \cdot \omega_r - (m_r + y_c \times n_r) \cdot \omega_r\}, \]  \( (26) \)
where \( \delta u_r, \delta u \) and \( \omega_r, \omega \) are the virtual translation and rotation vectors of \( M \) evaluated at the points \( x_c, x_i \in M \), respectively.

4.2. Entirely simply connected junction

The junction is called entirely simply connected along \( \Gamma \) if only \( u \) is continuous at \( \Gamma \) but \( Q \) is not constrained when approaching \( \Gamma \) along a path on each \( M_k \), see Fig. 3.

In this case, when approaching \( \Gamma \) we have to satisfy the following independent static continuity conditions:
\[ M_k v_k = 0, \quad k = 1, 2, 3. \]  \( (27) \)

Then, besides of (23), the third and fourth terms of S-JI integral identically vanish
\[ [Mv \cdot \omega] = 0, \quad [Mv] \cdot \omega_r = 0. \]  \( (28) \)

The relations (23) and (28) mean that the S-JI integral vanishes as well and the corresponding PVW reduces to (26). In this case the relation of any \( Q_k \) to the rotation field \( Q_r \) cannot be uniquely established, because definition of \( Q_r \) itself is not unique.

4.3. Partly simply supported junction

The shell junction can be called partly simply supported along \( \Gamma \) if \( u \) is continuous at \( \Gamma \), one of \( Q_k \) is not constrained while the remaining two of \( Q_k \) are assumed to coincide with \( Q_r \) when \( \Gamma \) is
approached. Since in our branching shell there are three branches $M_3$, each of them may be regarded as simply supported in the junction $\Gamma$, while the remaining two are then assumed to be stiffly connected with each other, see Fig. 4.

Let us assume, for definiteness, that the branches $M_1$ and $M_2$ are stiffly connected with each other and the branch $M_3$ is simply supported, see Fig. 4(b). Then the continuity conditions along $\Gamma$ become

$$u_i = u_\Gamma, \quad Q_3 = Q_\Gamma, \quad M_3 v_3 = 0,$$

$$\delta u_i = \delta u_\Gamma, \quad \omega_1 = \omega_2 = \omega_\Gamma, \quad \omega_3 = \omega_\Gamma.$$  (29)

Let $\nu_\Gamma, \tau_\Gamma, n_\Gamma$ be the orthonormal triad along $\Gamma$ that defines $Q_\Gamma$; with $\tau_\Gamma$ tangent to $\Gamma$ in the positive direction as in Fig. 1(b). Then choosing orientations of $M_1$ and $M_2$ defined by the unit normals $n_1$ and $n_2$ and taking $n_\Gamma = n_1 \times n_2$, as is shown in Fig. 4(b), we may relate $\nu_\Gamma$ to the respective $v_1$ and $v_2$ according to

$$\nu_\Gamma = \nu_\Gamma \times n_\Gamma = -\frac{1}{\cos \alpha} v_1 = +v_2,$$  (30)

where $\alpha$ is the angle between $v_1$ and the tangent space $T_{\nu_\Gamma}M_2$ along $\Gamma$, see Fig. 4(b). In this case, within the Lagrangian description used in the PVW (21) we obtain

$$[Mv \cdot \omega] = (M_1 v_1) \cdot \omega_1 + (M_2 v_2) \cdot \omega_2 + (M_3 v_3) \cdot \omega_3$$

$$= \{ (M_2 - M_1 \cos \alpha) v_1 \} \cdot \omega_\Gamma + \{ [Mv] \} \cdot \omega_\Gamma,$$  (31)

and this term cancels out with the last term in the S-JI integral of (21). Then the curvilinear S-JI integral (21) vanishes as well leading to the same form (26) of the PVW as for the stiff and entirely simply connected junctions. However, now $Q_3$ is defined by the kinematic continuity conditions (29) while $Q_\Gamma$ can be found only in the process of solution of the boundary value problem, in which the static continuity conditions $M_3 v_3 = 0$ is taken into account.

5. Deformable junctions

Let us discuss again the junction of the branching shell for which the translational continuity conditions $u_i = u_\Gamma$ still hold along $\Gamma$ and the rotation tensor $Q_\Gamma$ of $\Gamma$ is defined again by two stiffly connected branches $M_1$ and $M_2$, so that $Q_3 = Q_\Gamma$. But now the branch $M_3$ is assumed to be connected along the junction $\Gamma$ in some deformable manner, Fig. 5.

The junction of $M_3$ is called deformable along $\Gamma$ if, besides of the continuity conditions given above, the edge couple vector $m_3 = M_3 v_3 \in E$ depends on $Q_3$. $Q_3$ and/or $\delta Q_3$ as follows:

$$m_3 = m_3 (Q_3, Q_\Gamma, \delta Q_3) \neq 0.$$  (32)

where $(\cdot)' = \frac{d}{d s} (\cdot)$ is derivative along $\Gamma$. Of course, higher-order derivatives and higher-order variations of $Q_3$ may enter the function $m_3$ as well, if necessary.

Let us discuss in more detail the influence of separate ingredients of the function $m_3$ on the form of S-JI integral of (21).

5.1. Elastic junction

The junction of $M_3$ is called elastic along $\Gamma$ if $m_3$ in (32) depends on $Q_3$ alone,

$$m_3 = m_3 (Q_3).$$  (33)

Using the results of Section 4.3, the moment terms in the S-JI integral with account of (33) can be given by

![Fig. 5. The junction of $M_3$ in undeformed (a) and deformed (b) placements.](image-url)
\[ [\mathbf{Mv} \cdot \omega] = \{(M_2 - M_1 \cos \alpha) v_1 \} \cdot \omega_T + \mathbf{m}_3(Q_3) \cdot \omega_T, \]
\[ [\mathbf{Mv}] \cdot \omega_T = \{(M_2 - M_1 \cos \alpha) v_1 \} \cdot \omega_T + \mathbf{m}_3(Q_3) \cdot \omega_T. \]  
(34)

For the elastic junctions of \( M_3 \) the S-JI integral in the PVW (21) should be replaced by
\[ S-JI = \int_{\Gamma} \mathbf{m}_3(Q_3) \cdot (\omega_T - \omega_T) ds. \]  
(35)

For some elastic junctions it is more appropriate to use the linear function \( \mathbf{m}_3 \),
\[ \mathbf{m}_3 = A \cdot Q_3 = \mathbf{A} \omega_3, \]  
(36)

where \( A \) and \( \mathbf{A} \) are given 3rd-order and 2nd-order junction stiffness tensors, respectively, composed of scalar coefficients, and \( \omega_3 = \omega/\phi \) is the equivalent finite rotation vector of \( \mathbf{Q}_3 \) with \( \phi \) as the angle of rotation about the rotation axis defined by the unit vector \( \mathbf{i} \). For such linearly elastic junction of \( M_3 \) the S-JI integral becomes
\[ S-JI = \int_{\Gamma} (A \cdot \mathbf{Q}_3) \cdot (\omega_T - \omega_T) ds = \int_{\Gamma} \phi(Ai) \cdot (\omega_T - \omega_T) ds. \]  
(37)

5.2. Non-locally elastic junction

The junction of \( M_3 \) is called non-locally elastic along \( \Gamma \) if \( \mathbf{m}_3 \) in (32) depends on \( Q_3 \) alone,
\[ \mathbf{m}_3 = \mathbf{m}_3(Q_3). \]  
(38)

Let us take into account that \( Q_3^T Q_3 - Q_3^T Q_3 = \mathbf{Q}_3(Q_3)^T \) is the skew tensor expressible through its axial vector \( \mathbf{k}_3 \) by, see Pietraszkiewicz and Badur (1983 f. (4.22)),
\[ \mathbf{Q}_3^T Q_3 = \mathbf{k}_3 \times 1, \quad \mathbf{k}_3 = \phi \mathbf{i} + (\sin \phi \mathbf{i} - (1 - \cos \phi) \mathbf{j} \times \mathbf{i}) \mathbf{j}, \]  
(39)

so that (38) can equivalently be expressed by
\[ \mathbf{m}_3 = \mathbf{m}_3(Q_3 \times 1). \]  
(40)

For the non-locally elastic junction the S-JI integral takes the form
\[ S-JI = \int_{\Gamma} \mathbf{m}_3(Q_3) \cdot (\omega_T - \omega_T) ds = \int_{\Gamma} \mathbf{m}_3(\mathbf{k}_3) \cdot (\omega_T - \omega_T) ds. \]  
(41)

If, in particular, the functions \( \mathbf{m}_3 \) in (38) and \( \mathbf{m}_3 \) in (40) are linear, then
\[ \mathbf{m}_3 = \mathbb{G} \cdot Q_3 = \mathbb{G} \mathbf{k}_3, \]  
(42)

where now \( \mathbb{G} \) and \( \mathbb{G} \) are known 3rd-order and 2nd-order stiffness tensors composed of scalar coefficients, respectively. For such non-locally linearly elastic junction the S-JI integral reads
\[ S-JI = \int_{\Gamma} (\mathbb{G} \cdot Q_3) \cdot (\omega_T - \omega_T) ds = \int_{\Gamma} (\mathbb{G} \mathbf{k}_3) \cdot (\omega_T - \omega_T) ds. \]  
(43)

5.3. Dissipative junction

The deformable junction of \( M_3 \) can be called dissipative along \( \Gamma \) if \( \mathbf{m}_3 \) in (32) depends on \( \delta Q_3 \) alone,
\[ \mathbf{m}_3 = \mathbf{m}_3(\delta Q_3). \]  
(44)

Taking again into account that \( Q_3^T \delta Q_3 = -(\mathbf{Q}_3^T \delta Q_3)^T \) is the skew tensor expressible through its axial vector \( \omega_3 \) by
\[ \mathbf{Q}_3^T \delta Q_3 = \omega_3 \times 1, \quad \omega_3 = (\delta \phi \mathbf{i} + (\sin \phi \mathbf{i} - (1 - \cos \phi) \mathbf{j} \times \mathbf{i}) \mathbf{j}) \delta \phi, \]  
(45)

the relation (44) can equivalently be expressed by
\[ \mathbf{m}_3 = \mathbf{m}_3(Q_3 \times 1) = \mathbf{m}_3(\omega_3). \]  
(46)

In this case the S-JI integral takes the form
\[ S-JI = \int_{\Gamma} \mathbf{m}_3(\delta Q_3) \cdot (\omega_T - \omega_T) ds = \int_{\Gamma} \mathbf{m}_3(\omega_3) \cdot (\omega_T - \omega_T) ds. \]  
(47)

If, in particular, the functions \( \mathbf{m}_3 \) in (44) and \( \mathbf{m}_3 \) in (46) are linear, then
\[ \mathbf{m}_3 = \mathbb{H} \cdot Q_3 = \mathbb{H} \omega_3, \]  
(48)

where again \( \mathbb{H} \) and \( \mathbb{H} \) are known 3rd-order and 2nd-order stiffness tensors composed of scalar coefficients, respectively. For such linearly dissipative junction the S-JI integral becomes
\[ S-JI = \int_{\Gamma} (\mathbb{H} \cdot Q_3) \cdot (\omega_T - \omega_T) ds = \int_{\Gamma} (\mathbb{H} \omega_3) \cdot (\omega_T - \omega_T) ds. \]  
(49)

6. Conclusions

It has been shown that the unique 2D kinematics of the branching shell consists of the translation vector \( \mathbf{u} \) and rotation tensor \( \mathbf{Q} \) fields defined on the regular parts of the shell base surface as well as of independent fields \( \omega_T, Q_3 \) defined along the singular surface curve \( \Gamma \) modelling the shell branching.

For the branching shell we have derived the 2D principle of virtual work (21), in which different types of junctions are taken into account by appropriate forms of the shell-junction interaction integral. It has been found that the S-JI integral vanishes for the stiff, entirely simply connected and partly simply supported junctions. In case of deformable junctions, the S-JI integral has been explicitly calculated for the elastic and dissipative junctions as well as for the non-locally elastic junction, and their particular linear behaviour is characterized as well.

The 2D principle of virtual work (21), with S-JI integrals corresponding to the particular type of junctions along \( \Gamma \), may be used to develop appropriate computer programs for analyses of branching shells with various types of junctions.
