(SOL), tibialis anterior (TA), vastus lateralis (VL), rectus femoris (RF) and hamstrings (HA) and were compared between lower limbs according to the degree of induce equinus. The data were divided into nine intervals in relation to the phases of the motion as described by Perry.

Results.-- On the lower limb with the orthosis, the activation of the SOL was earlier from 73–100% and 0–50% of the cycle (coactivation SOL-TA) and the amplitude increase from −10° of dorsiflexion (P < 0.01). From 0 to 10% of cycle, the TA amplitude decreases from −20° (P < 0.01). From −10° of dorsiflexion, the HA activation significantly increase from 0 to 10% of the cycle. The DA activation decrease from 0 to 10% cycle (P < 0.05) and like the VL, a muscular activation appear in the middle of stance phase −20° (VL 20–30%; P < 0.05). The contralateral limb, SOL activated earlier from 87–100% and 0–10% at MP (P < 0.01).

Discussion.-- Equinus gait secondary to the orthosis induced changes in muscle activation both in terms of timing and in terms of signal amplitude. The premature activity of SOL, the TA-SOL coactivation and the reduce TA amplitude are frequently observed during cerebral palsy gait. These findings in healthy children show that a foot deformation without neurological disturbance induce primary changes in muscle activation, which must be taken into account during interpretation in motion analysis.

Peroneus longus and the midfoot in children: EMG normative data
Plate forme d’analyse de la motricité, pôle médico-chirurgical pédiatrique, CHU Timone-Enfants, 264, rue Saint-Pierre, 13385 Marseille, France

Keywords: Mid foot; Children; Peroneus longus; Dynamic EMG; Gait
Introduction.-- The EMG overactivity of peroneus longus (PL) is described [1] as the major deforming force in spastic midfoot break in adult after stroke. Before to test this hypothesis in children with cerebral palsy (CP), it was necessary to provide the normal EMG activity of PL in children without neuromuscular disorders. These data are not studied in literature. It was necessary to provide the normal EMG activity of PL in CP children without neuromuscular disorders before to study its overactivity in CP especially in the midfoot break.

Materials and methods.-- One thousand one hundred and four strides of 21 children (age 6.5yrs ± 1) without neuromuscular disorders were examined using surface EMG during walking. The PL activity was normalized as a percentage during strides. A software selected the more repeatable strides. The onset, offset activity of rectified raw EMG signal was detected by a manual selection: the threshold was 20 μV [3].

Results.– Resulting in 1104 normal strides: the mean toe off was at 62.8%, the PL onset activity was at 26.8% in midstance and the offset at 52.2% during terminal stance. There was never activity during swing phase.

Discussion.– These data confirmed the PL activation as a locking effect on midfoot, in midstance during the ankle rocker for progression and without motor action on the ankle [4]: PL supports the longitudinal and transversal arches. In terminal stance during footoff rocker for progression, PL has a locking effect on the first ray: the foot is stabilising during the heel rise. It prevents excessive inversion thus maintaining the first metatarsal down on the ground. PL maintains the stabilisation of the first and second ray by a pronation to counteract the lift effect of the supination muscles. The PL contraction should be rather isometric.

Conclusion.– PL EMG activation provides, during mid stance, a locking effect on the midfoot and in terminal stance a stabilising effect on the footoff after heel rise [2]. Thus the relation between PL overactivity and midfoot break has to be assessed in CP children.

Impairment profile of shoulder muscle strength in children with brachial plexus palsy at birth

Keywords: Brachial plexus palsy; Shoulder; Strength; Children
Introduction.-- Brachial plexus palsy (BPP) at birth can lead to severe functional limitations of the whole upper-limb. Although shoulder muscle strength loss and imbalance are central to the loss of upper-limb function associated with BPP, biomechanical and clinical assessments of muscle strength are rarely reported for this population. Thus, the aim of this study was to quantitatively evaluate the muscle strength impairment profile in a group of children with unilateral BPP. In addition, the validity and reliability of the current methodologies was tested.

Methods.– Ten children with unilateral BPP (mean age = 12.31, SD = 3.28) underwent the following assessments in both shoulders: (1) three trials of maximal isometric contractions in flexion/extension, internal/external rotation, and abduction/adduction using a hand held dynamometer, (2) maximal isometric contractions of flexion/extension using a Biodes®. The maximal values of the involved shoulder were compared to the non-involved one.

Results.– The concurrent validity between the hand held dynamometer and Biodes® measures was excellent (r² = 0.81). The inter-trial reliability was also excellent (ICC between 0.94 and 0.98), regardless of the direction and side. The comparison between sides showed significant differences in all directions (P-values ranged from 0.036-0.0009), except for flexion. External rotation and extension were the most impaired directions, with average strength impaired/ non impaired shoulder ratios of 30% and 40%.

Discussion.– This study provides the first comprehensive quantitative measurement of shoulder muscle strength using a handheld and motorized dynamometer in children with BPP. Future work will relate specific patterns of weakness to resultant bony and muscle deformity and functional limitations.

T-score computer-calculation in Goal Attainment Scales does not provide further information than hand-calculation of simple mean scores: Analysis of 537 GAS scales

Keywords: GAS; Personal goals; Scale; Botulinum toxin
Goal Attainment Scaling (GAS) is a method of measuring progress towards individual goals. GAS is originally a 5-points scale, that represent baseline and different levels of goal attainment. It is possible to calculate by an Excel calculation sheet a T-score that gives the overall result of the different scales of one patient using Kiresuk’s formulae. The aim of this study was to compare T-scores and simple means of GAS raw scores.

For 2 years all patients, aged 2–20 presenting a motor handicap that needed botulinum toxin treatment were included. One to seven GAS scales were written per patients and results were assessed 8 weeks after treatment. T-scores were
calculated using Kiresuk’s formulae considering that all GAS scores had the same importance (non weighted T-score) or weighting GAS scores according to its importance for participation and activity (weighted T-score). Means of raw scores were then calculated according to the same weighting criteria. Normal distribution of T-scores and means were assessed by a Kolmogorov-Smirnov test and their correlation by Spearman’s Rho.

A total of 541 GAS scales were included, out of which 537 GAS have been analyzed, concerning 139 botulinum treatments. T-scores (56.77 ± 10.2) and means of raw scores (0.49 ± 0.74) were highly correlated (P = 0.99). Weighted T-scores and weighted means had a normal distribution. Non weighted T-scores and means did not have a normal distribution (P = 0.013 and 0.011).

As T-scores and means of raw scores were highly correlated in our study, it seems sensible to replace T-score calculation by a simple manual calculation of a mean of raw scores in clinical daily practice. Calculating T-scores does not necessarily imply that the distribution of T-scores will have a normal distribution. Implication are discussed in term of group effects interpreted through T-scores.

Keywords: Plagiocephaly; Torticollis; Infant; Mattress

Introduction.—The rising incidence of plagiocephaly is documented since 1992 and the adoption of supine sleep position. The present therapy included repositioning interventions and physiotherapy orthotic. An exclusive cranial correction (helmet) is widely accepted in severe positional plagiocephaly with variable tolerance. We developed a mattress to act to plagiocephaly and also the limited head rotation.

Method.—A prospective study of 18 infants (middle-age: 5 months) with nonsynostotic plagiocephaly and limited head rotation. Two-dimensional head tracings were taken for each infant, before and after therapy. We obtained Cephalic Index (CI) for the brachycephaly and Cranial Vault Asymmetry Index (CVAI), and we classified each infant in five degree of severity of plagiocephaly (five is the most severe) with the CVAI.

Results.—After therapy we obtained a decrease of CVAI 8.69 to 5.33 (P < 0.0001, paired t test) and plagiocephaly severity degree 3.6 to 5.33 (P < 0.0001, paired t test) without modification of CI 0.91 versus 0.92 (P = 0.503, paired t test). The result is correlated to the beginning age of therapy (Spearman r = 0.70, P = 0.008). More the therapy begins early more it’s effective.

Discussion and conclusion.—We demonstrated the efficacy of the mattress for the cranial asymmetry. The mattress doesn’t increase the brachycephaly (CI). We confirmed the advantage of an early therapy.
