Background: Non-specific chest symptoms associated with coronary artery spasm (CAS) remain underdiagnosed and consequently undertreated. Our center applies a policy of systematic CAS detection by provocative tests (PT) in normal or near normal coronary arteries in patients with symptoms compatible with vasospastic origin. We retrospectively studied the prevalence of CAS, safety of PTs and patient outcome over a 10-year period.

Methods: From December 2002 to July 2012, 13,902 patients underwent 18,454 coronary angiographies. 5,962 of these patients with normal or near normal arteries underwent 2,397 PTs. 256 were consequentially diagnosed with CAS (10.7%). In addition, among the 7,940 patients with ≥50% stenosis on coronary angiography, 44 patients were diagnosed as having a spontaneous CAS (0.6%).

Results: Compared to the overall population, patients with CAS were more often female (44.7% vs. 20.6%; p=0.0001), younger (55 [47.5-64] vs. 61 [52-70] years; p=0.0001), and more often smokers (63.7% vs. 42.3%; p<0.0001). Initial presentation was more frequently acute coronary syndrome (37.4% vs. 28.9%) and non-specific chest pain (41.8% vs. 21.6%). Sixty-nine patients had refractory CAS when PT was abnormal under antispastic treatment. 99.1% of the patients who underwent a PT had an event-free hospital course. At 46 months, the all-cause death rate, myocardial infarction, stroke and revascularization in CAS patients were 4.3%, 3.3%, 0% and 4.3%, respectively.

Conclusions: This retrospective study of 10 years of experience suggests that CAS is present in as many as 10.7% of patients with chest symptoms at rest. PT seems to be safe in patients with normal or near normal coronary angiography. These findings could justify performing PTs more systematically in this setting to avoid the potentially severe outcomes of undiagnosed CAS.

Deferred Coronary Lesion With A Gray Zone Fractional Flow Reserve In Patients With Intermediate Stenosis Is At Higher Risk Of Future Coronary Events

Background: Deferral of revascularization of an intermediate coronary stenosis with fractional flow reserve (FFR) ≥0.75 was reported to be safe. However, the FFR value range between 0.75 and 0.80 has been recognized as a gray zone. We hypothesized that outcomes after deferral of revascularization between coronary lesions with gray zone FFR and those with non-ischemic FFR (<0.80) might be different. The aim of this study was to evaluate the clinical outcomes of patients with intermediate coronary stenosis with gray zone FFR compared to those with FFR >0.80.

Methods: We reviewed medical records of patients who underwent an FFR measurement at our hospital between January 2008 and December 2011. Long-term outcomes of 153 patients with angiographically intermediate coronary lesions deferred from revascularization on the basis of an FFR > 0.75 were obtained. We divided the patients into two groups. Gray zone group consisted of 57 patients with FFR values between 0.75 to 0.80. Non-ischemia group comprised 96 patients with FFR values above 0.80. The outcome of the gray zone group was compared with that of the non-ischemia group. The primary endpoint of this study was target vessel failure (TVF) defined as cardiac death, target vessel related myocardial infarction, and ischemia-driven target vessel revascularization.

Results: There were no differences in baseline clinical characteristics between the two groups. Mean FFR value of deferred lesions was significantly lower in the gray zone group than the non-ischemia group (0.78 ± 0.02 vs. 0.88 ± 0.05). During a mean follow-up period of 2.8 ± 1.2 years, TVF occurred in 11 deferred lesions (7.2%). The incidence of TVF was significantly different between two groups: 14.0% in the gray zone group and 0.7% in the non-ischemia group (hazard ratio: 10.73, 95% confidence interval, 1.04 to 15.603; p = 0.043).

Conclusions: Not all deferred lesions based on FFR ≥ 0.75 were equally safe during the follow up period. Patients with deferred coronary lesions with the gray zone FFR had higher risk of TVF in the future than those with FFR >0.80.
