Let $T$ be a quasidiagonal operator on a separable Hilbert space. It is shown that there exists a sequence of operators $\{T_n\}$ such that $\dim(C^*(T_n)) < \infty$ and $\|T - T_n\| \to 0$ if and only if $C^*(T)$ is exact.

1. INTRODUCTION

Let $H$ be a separable Hilbert space and $B(H)$ denote the bounded operators on $H$. $T \in B(H)$ is called block diagonal if there exists an increasing sequence of finite rank projections $P_1 \leq P_2 \leq \cdots$ such that $P_n T - T P_n = 0$ for all $n$ and $P_n \to 1_H$ (s.o.t.). $T \in B(H)$ is called quasi-diagonal if it is the norm limit of a sequence of block diagonal operators.

Herrero asked whether every quasidiagonal operator is the norm limit of operators $T_n$ such that the $C^*$-algebra generated by each $T_n$ is finite dimensional. This is equivalent to asking if quasidiagonal operators are always norm limits of block diagonal operators each of which is comprised of blocks of bounded dimension. (See [Vo2; Section 5] for a nice discussion of this problem, [DHS] for equivalent formulations, and [Vo2], [Br] for the basic theory of quasidiagonal (sets of) operators.) A negative answer was first obtained by Szarek (cf. [Sz]). Using probabilistic methods he was able to show the existence of a quasidiagonal operator for which there was an operator theoretic obstruction to such approximations. In [Vo1] Voiculescu observed an operator algebraic obstruction to the existence of such approximations which we now recall.

1 Currently an MSRI Postdoctoral Fellow.
Assume $T_n \to T$ (in norm) and $\dim(C^*(T_n)) < \infty$ for all $n$. Let $E_n: B(H) \to C^*(T_n)$ be conditional expectations (which exist by finite dimensionality). It follows that $E_n(x) \to x$ (in norm) for every $x \in C^*(T)$ and hence the inclusion $C^*(T) \hookrightarrow B(H)$ is a nuclear map. Thanks to the work of Kirchberg, this latter condition is equivalent to saying that $C^*(T)$ is an exact $C^*$-algebra (cf. [Wa]). Hence, exactness provides a natural operator algebraic obstruction to Herrero’s approximation question. In this paper we observe that this is the only obstruction.

**Theorem 1.1.** If $T$ is a quasidiagonal operator on a separable Hilbert space, then $T$ is the norm limit of operators $\{T_n\}$ such that $\dim(C^*(T_n)) < \infty$ for every $n$ if and only if $C^*(T)$ is exact.

This gives an affirmative answer to [DHS, Problem 4.3] and is an immediate consequence of the following answer to a question of Dadarlat (cf. [Da]).

**Theorem 1.2.** Let $A$ be an exact $C^*$-algebra and $\psi: A \to B(H)$ be a $\ast$-homomorphism with $H$ separable. Then $\psi(A)$ is a quasidiagonal set of operators if and only if for each $\epsilon > 0$ and finite set $F \subset A$ there exists a finite dimensional $C^*$-subalgebra $C \subset B(H)$ with $\psi(F) \subset C$ (i.e., for each $a \in F$ there exists $c \in C$ with $\|\psi(a) - c\| < \epsilon$).

Dadarlat proved Theorem 1.2 under the additional assumption that $\psi(A)$ contains no nonzero compact operators (cf. [Da, Thm. 6]). We will deduce the general case from Dadarlat’s result and a technical generalization of Voiculescu’s noncommutative Weyl–von Neumann Theorem.

**2. PROOFS OF MAIN RESULTS**

If $A$ is a separable, unital $C^*$-algebra and $\varphi: A \to B(H)$ (with $H$ separable and infinite dimensional) is a unital completely positive map then we say that $\varphi$ is a **faithful representation modulo the compacts** if $\varphi: A \to Q(H)$ is a $\ast$-monomorphism, where $\pi$ is the quotient map onto the Calkin algebra. In this situation we define constants $\eta_\varphi(a)$ by

$$\eta_\varphi(a) = 2 \max(\|\varphi(a^*a) - \varphi(a)\varphi(a)\|^{1/2}, \|\varphi(aa^*) - \varphi(a)\varphi(a^*)\|^{1/2})$$

for every $a \in A$. The following lemma is the generalization of Voiculescu’s Theorem that we will need. The main idea in the proof is essentially due to Salinas (see the proofs of [Sa, Thm. 2.9] and [DHS, Thm. 4.2]). This result also appears in [Br], but we include the proof for the reader’s convenience.
Lemma 2.1. Let $A$ be a separable, unital $C^*$-algebra and $\varphi: A \to B(H)$ be a faithful representation modulo the compacts. If $\sigma: A \to B(K)$ is any faithful, unital, representation such that $\sigma(A)$ contains no nonzero compact operators then there exist unitaries $U_n: H \to K$ such that

$$\limsup_{n \to \infty} \|\sigma(a) - U_n \varphi(a) U_n^*\| \leq \eta_\varphi(a)$$

for every $a \in A$.

Proof. Note that by the usual version of Voiculescu’s Theorem it suffices to show that there exists a representation $\sigma$ satisfying the conclusion of the theorem since all such representations are approximately unitarily equivalent.

Let $\rho: A \to B(L)$ be the Stinespring dilation of $\varphi$; i.e., $\rho$ is a unital representation of $A$ and there exists an isometry $V: H \to L$ such that $\varphi(a) = V^* \rho(a) V$, for all $a \in A$. Let $P = VV^* \in B(L)$ and $P^\perp = 1_L - P$. A routine calculation shows that for every $a \in A$,

$$\|P^\perp \rho(a) P\| \leq \|\varphi(a^* a) - \varphi(a^*) \varphi(a)\|^{1/2}. \quad (1)$$

Now write $L = PL \oplus P^\perp L$ and decompose the representation $\rho$ accordingly. That is, consider the matrix decomposition

$$\rho(a) = \begin{pmatrix} \rho(a)_{11} & \rho(a)_{12} \\ \rho(a)_{21} & \rho(a)_{22} \end{pmatrix},$$

where $\rho(a)_{21} = P^\perp \rho(a) P$ and $\rho(a)_{12} = \rho(a^*)_{21}$.

Consider the Hilbert space $P^\perp L \oplus PL$ and the representation $\rho': A \to B(P^\perp L \oplus PL)$ given in matrix form as

$$\rho'(a) = \begin{pmatrix} \rho(a)_{22} & \rho(a)_{21} \\ \rho(a)_{12} & \rho(a)_{11} \end{pmatrix}.$$

Now using the obvious identification of the Hilbert spaces

$$PL \oplus \left( \bigoplus_N P^\perp L \oplus PL \right) \quad \text{and} \quad \bigoplus_N L = \bigoplus_N (PL \oplus P^\perp L)$$

a standard calculation (using inequality (1) above and the fact that $\rho(a)_{21} = P^\perp \rho(a) P$ while $\|\rho(a)_{12}\| = \|\rho(a^*)_{21}\|$) shows that

$$\|\rho(a)_{11} \oplus \rho'^\infty(a) - \rho^\infty(a)\| \leq \eta_\varphi(a)$$

for all $a \in A$, where $\rho'^\infty = \bigoplus_N \rho'$ and $\rho^\infty = \bigoplus_N \rho$. Note also that $\rho(a)_{11} = V \varphi(a) V^*$. 

362 NATHANIAL P. BROWN
Now, let $C$ be the linear space $\varphi(A) + \mathcal{K}(H)$. Note that $C$ is actually a separable, unital $C^*$-subalgebra of $B(H)$ with $\pi(C) = A$, where $\pi: B(H) \to Q(H)$ is the quotient map onto the Calkin algebra. By Voiculescu’s Theorem we have that $1 \otimes \rho^{\infty} \circ \pi$ is approximately unitarily equivalent modulo the compacts to $1$, where $1 : C \hookrightarrow B(H)$ is the inclusion. Let $W_n : H \to H \otimes (\bigoplus_n (P^2 L \oplus PL))$ be unitaries such that

$$\|\varphi(a) \otimes \rho^{\infty}(a) - W_n \varphi(a) W_n^*\| \to 0$$

for all $a \in A$.

Let

$$\tilde{V} : H \to \bigoplus_n (P^2 L) \to \bigoplus_n L$$

be the unitary $V \oplus 1$ (again using the obvious identification of $PL \oplus (\bigoplus_n (P^2 L \oplus PL))$ and $\bigoplus_n L$). Note that $\tilde{V}(\varphi(a) \otimes \rho^{\infty}(a)) \tilde{V}^* = V \varphi(a) V^* \otimes \rho^{\infty}(a) = \rho(a) \otimes \rho^{\infty}(a)$. We complete the proof by defining

$$K = \bigoplus_n L, \quad \sigma = \rho^{\infty} = \bigoplus_n \rho, \quad U_n = \tilde{V} W_n : H \to \bigoplus_n L = K.$$

**Proof of Theorem 1.2.** We may assume that $A$ is separable unital and $\pi$ is a unital $*$-homomorphism. Since quotients of exact $C^*$-algebras are again exact it suffices to prove that if $A \subset B(H)$ is an exact $C^*$-algebra and a quasidiagonal set of operators then for each finite set $\mathcal{F} \subset A$ and $\epsilon > 0$ there exists a finite dimensional subalgebra $C \subset B(H)$ such that $\mathcal{F} \subset \epsilon C$. In fact, it suffices to show that $\mathcal{F} \subset \epsilon C$, where $C$ is an approximately finite dimensional (AF) $C^*$-subalgebra of $B(H)$.

Let $P_1 \leq P_2 \leq P_3 \ldots$ be an increasing sequence of finite rank projections which converge to the identity operator in the strong operator topology and such that $\|aP_n - P_n a\| \to 0$ for all $a \in A$. Let $B \subset Q(H)$ be the image of $A$ in the Calkin algebra. Then we have the natural exact sequence $0 \to \mathcal{K}(H) \to A + \mathcal{K}(H) \to B \to 0$. Since $\mathcal{K}(H)$ and $B$ are exact and the quotient map $A + \mathcal{K}(H) \to B$ is locally liftable (since $A$ is exact), it follows from [Ki2, Prop. 7.1] that $A + \mathcal{K}(H)$ is also exact. Since the compact operators are actually nuclear it follows from [EH], that this short exact sequence is semisplit; i.e., there exists a unital completely positive splitting $\varphi : B \to A + \mathcal{K}(H)$. Define $\varphi_n(a) = (1 - P_n) \varphi(a)(1 - P_n)$ and note that each $\varphi_n$ is also a completely positive splitting. Moreover (as is well known) the maps $\varphi_n$ are asymptotically multiplicative and hence $B$ is a quasidiagonal (QD) $C^*$-algebra. Let $H_n = (1 - P_n) H$. Note that each $H_n$ has finite codimension in $H$. 

HERRERO’S APPROXIMATION PROBLEM 363
Let \( \rho: B \to B(K) \) be a faithful representation such that \( \rho(B) \) contains no nonzero compact operators. By Dadarlat’s result ([Da, Thm. 6]), we can find a sequence of finite dimensional \( C^* \)-subalgebras \( D_n \subset B(K) \) such that each element of \( \rho(B) \) is the norm limit of a sequence taken from the algebras \( D_n \). Since the maps \( \varphi_n \) are asymptotically multiplicative faithful representations modulo the compacts (when regarded as taking values in \( B(H_n) \)) and each \( H_n \) has finite codimension in \( H \) it follows from Lemma 2.1 that we can find a sequence of finite dimensional \( C^* \)-subalgebras \( E_n \subset Q(H) \) such that each element of \( B \) is the norm limit of a sequence taken from the algebras \( E_n \). Since extensions of AF algebras are again AF the proof of the theorem is completed by defining \( C_n \) to be the pullbacks of the \( E_n \).

In [Sa] N. Salinas defined \( Ext_{qd}(B) \) for a QD \( C^* \)-algebra as follows. A unital \(*\)-monomorphism \( \rho: B \to Q(H) \) defines an element of \( Ext_{qd}(B) \) if the pullback of \( \rho(B) \) in \( B(H) \) is a quasidiagonal set of operators. It is easy to see that this notion in invariant under strong (unitary) equivalence of extensions (i.e. gives a well-defined subset of \( Ext(B) \)). When \( B \) is nuclear, \( Ext_{qd}(B) \) is a subgroup of \( Ext(B) \) (cf. [Sa, Cor. 2.10]). Kirchberg has given examples of exact QD \( C^* \)-algebras \( B \) and \(*\)-monomorphisms \( \rho: B \to Q(H) \) which define noninvertible elements of \( Ext_{qd}(B) \) (cf. [Ki1]).

Corollary 2.2. Let \( B \) be a separable unital exact QD \( C^* \)-algebra and \( \rho: B \to Q(H) \) be a \(*\)-monomorphism such that \([\rho]\) \( \in Ext_{qd}(B) \). Then \([\rho]\) is invertible if and only if for each finite subset \( \mathcal{F} \subset B \) and \( \epsilon > 0 \) there exists a finite dimensional \( C^* \)-subalgebra \( C \subset Q(H) \) such that \( \rho(\mathcal{F}) \subset \epsilon/4 \cdot C \).

Proof. If \([\rho]\) is invertible then there exists a completely positive splitting and hence the proof of Theorem 1.2 shows that \( \rho(B) \) admits such approximants. On the other hand, if \( \rho(B) \) admits such approximants then the argument in the introduction shows that \( \rho \) is a nuclear map and hence, by the Choi–Effros Lifting Theorem, is liftable (hence invertible).

We thank Dadarlat (personal communication) for pointing out the following example.

Example 2.3. Let \( H \) be a Hilbert space with orthonormal basis \( \{e_i\}_{i \in \mathbb{Z}} \). Let \( U \in B(H) \) be the bilateral shift unitary (i.e., \( U(e_i) = e_{i+1} \)) and \( T \in B(H) \) be any operator with the property that each \( e_i \) is an eigenvector for \( T \). If we define \( S = TU \) then \( C^*(S) \) is exact. This is because it is contained in a nuclear \( C^* \)-algebra. More precisely, the \( C^* \)-algebra generated by \( U \).
and the set of all such $T$ (as above) is naturally isomorphic to the crossed product $C^*$-algebra $L^\infty(Z) \rtimes \mathbb{Z}$, where the action $\gamma$ on $L^\infty(Z)$ arises from the bilateral shift $i \mapsto i + 1$ on $\mathbb{Z}$. Since crossed products of nuclear $C^*$-algebras by amenable groups are again nuclear, this shows that $C^*(S) \subset L^\infty(Z) \rtimes \mathbb{Z}$ is an exact $C^*$-algebra. Evidently this example extends to one-sided (i.e., unilateral) shifts as well since these correspond to crossed products by endomorphisms (which still preserves nuclearity).

The example above is nothing but the class of weighted shift (both bilateral and unilateral) operators. Smucker first characterized the quasi-diagonality of weighted shifts in terms of the associated weight sequence in [Sm]. Thus our main result gives a new proof of a result of Herrero who showed that all quasidiagonal weighted shifts admit Herrero approximations (see [He]). Note, however, that the present approach has the added benefit of treating $n$-tuples as well. That is, our results show that if $S_1, \ldots, S_k$ are weighted shifts (with respect to the same basis) and \{\(S_1, \ldots, S_k\)\} is a quasidiagonal set of operators then for each $\epsilon > 0$ there exist operators $\tilde{S}_1, \ldots, \tilde{S}_k$ such that $\|S_i - \tilde{S}_i\| < \epsilon$ and $C^*(\tilde{S}_1, \ldots, \tilde{S}_k)$ is finite dimensional (since $C^*(S_1, \ldots, S_k)$ will always be exact).
