\textbf{Abstract}

In this paper we study abstract elementary classes of modules. We give several characterizations of when the class of modules $A$ with $\text{Ext}^i(A, N) = 0$ (for fixed $N$ and all $i$) is abstract elementary class with respect to the notion that $M_1$ is a strong submodel $M_2$ if the quotient remains in the given class.

\textbf{Keywords:} Abstract elementary class; ⊥N; Cotorsion pairs model; Theory of modules

We show that the concept of an Abstract Elementary Class (AEC) provides a unifying notion for several properties of classes of modules and discuss the stability class of these AEC. An abstract elementary class consists of a class of models $K$ and a strengthening of the notion of submodel $\prec_{K}$ such that $(K, \prec_{K})$ satisfies the properties described below. Here we deal with various classes $(⊥N, \prec_{N})$; the precise definition of the class of modules $⊥N$ is given below. A key innovation is that $A \prec_{N} B$ means $A \subseteq B$ and $B/A \in ⊥N$.

We define in the text the main notions used here; important background definitions and proofs from the theory of modules can be found in [10] and [12]; concepts of AEC are due to Shelah (e.g. [19]) but collected in [4].

The surprising fact is that some of the basic model theoretic properties of the class $(⊥N, \prec_{N})$ translate directly to algebraic properties of the class $⊥N$ and the module $N$ over the ring $R$ that have previously been studied in quite a different context (approximation theory of modules, infinite dimensional tilting theory etc.). Our main results, stated with increasingly strong conditions on the ring $R$, are:

\textbf{Theorem 0.1.}

(1) Let $R$ be any ring and $N$ an $R$-module. If $(⊥N, \prec_{N})$ is an AEC then $N$ is a cotorsion module.

Conversely, if $N$ is pure injective, then the class $(⊥N, \prec_{N})$ is an AEC.

(2) Let $R$ be a right noetherian ring and $N$ be an $R$-module of injective dimension $\leq 1$. Then the class $(⊥N, \prec_{N})$ is an AEC if and only if $⊥N$ is closed under direct limits (of arbitrary homomorphisms).

(3) Let $R$ be a Dedekind domain and $N$ an $R$-module. The class $(⊥N, \prec_{N})$ is an AEC if and only if $N$ is cotorsion.
Since the ring of integers is a Dedekind domain, Theorem 0.1.3 exactly characterizes the abelian groups \( N \) such that \((\langle N \rangle, \prec_N)\) is an AEC. We write "conversely" in Theorem 0.1(1), although it is only a partial converse; every pure-injective module is cotorsion, but cotorsion modules are not necessarily pure injective.

**Theorem 0.2.**

1. For any module \( N \), \((\langle N \rangle, \prec_N)\) has the amalgamation property.
2. Let \( N \) be a module of injective dimension \( \leq 1 \). Then \((\langle N \rangle, \prec_N)\) is an AEC that admits intersections iff \( \langle N \rangle \) is closed under direct products iff \( \langle N \rangle \) is a cotilting class. In this case \( \langle N \rangle \) is first order axiomatizable.
3. Assume that \( R \) is a Dedekind domain. Then each AEC of the form \((\langle N \rangle, \prec_N)\) admits intersections. Moreover, \( \langle N \rangle \) coincides with the (first order axiomatizable) class \( K(P) \) for a set \( P \) consisting of maximal ideals, and the closure, \( cl_M(X) \), coincides with the set of all \( m \in M \) such that the ideal \( \{ r \in R : mr \in X \} \) is a finite product of elements of \( P \).

Conversely, for any set \( P \) of maximal ideals, there is a pure-injective module \( N \) such that \((\langle N \rangle, \prec_N)\) is an AEC with \( \langle N \rangle = K(P) \).

Here, given a Dedekind domain \( R \) and a maximal ideal \( p \), we call a module \( M \) \( p \)-torsion free provided that the module \( R/p \) does not embed into \( M \). For a set of maximal ideals \( P \), \( K(P) \) is defined as the class of all modules that are \( p \)-torsion free for all \( p \in P \).

For example, if \( P = \emptyset \) then \( \langle N \rangle = K(P) \) is the class of all modules and \( \prec_N = \prec_{K(P)} \) is the submodule relation. If \( P \) is the set of all maximal ideals of \( R \) then \( \langle N \rangle = K(P) \) is the class of all torsion-free modules and \( \prec_N = \prec_{K(P)} \) is the relation of being a pure submodule. It is easy to see that for different choices of \( P \) we get distinct classes \( K(P) \).

In the case of abelian groups (that is, modules over the ring of integers \( Z \)), or more generally, modules over a principal ideal domain (p.i.d.), we can say more.

**Theorem 0.3.**

1. If \( P \) is a nonempty set of prime ideals in \( Z \) then \((K(P), \prec_{K(P)})\) is \((\aleph_0, \infty)\)-tame, and if \( \lambda \) is an infinite cardinal, then \((K(P), \prec_{K(P)})\) is stable in \( \lambda \) if and only if \( \lambda^{\aleph_0} = \lambda \).
2. More generally, if \( R \) is a principal ideal domain, and \( P \) is a nonempty set of prime ideals in \( R \) with \( |P| = \kappa \), then \((K(P), \prec_{K(P)})\) is \((LS(K(P)), \infty)\)-tame, and if \( \lambda \) is an infinite cardinal, then \((K(P), \prec_{K(P)})\) is stable in \( \lambda \) if and only if \( \lambda^{\aleph_0 + \omega} = \lambda \).

We discuss Theorem 0.1 in Section 1, Theorem 0.2 in Section 2, and Theorem 0.3 in Section 3.

The notion of an abstract elementary class, AEC, is usually viewed as an abstract version of ‘complete first order theory’ suitable for studying the class of models of a sentence in infinitary logic. However, the ‘completeness’ is not at all inherent in the notion. This work was stimulated by the discussion at the AIM conference on Abstract Elementary Classes in July 2006 of abelian groups as AEC (see [5]). One of the goals of that conference was to identify some naturally occurring classes of abelian groups that form AEC under an appropriate notion of strong substructure. This paper provides a collection of such examples. We show certain variants of ‘cotorsion pairs’ of modules often satisfy the conditions for an AEC and classify when this happens. These examples provide a new type of strong extension; most previous examples are ‘elementary submodel’ in various logics. And as we describe in the last two sections, these examples provide further insight into the notion of Galois type. In particular, they provide examples when the notion of the Galois type of an element is readily translated into a syntactic type of a sequence.

1. **When is \((\langle N \rangle, \prec_N)\) an AEC?**

   We will begin by describing the main concepts, then prove the theorem. We recall the precise definition of an AEC since checking these axioms is the main content of this section. For background on AEC see e.g. [13,4,19,20].

**Definition 1.1.** A class of \( \tau \)-structures, \((K, \prec_K)\), is said to be an **abstract elementary class** (AEC) if both \( K \) and the binary relation \( \prec_K \) on \( K \) are closed under isomorphism and satisfy the following conditions:

- **A1.** If \( M \prec_K N \) then \( M \subseteq N \).
- **A2.** \( \prec_K \) is a partial order on \( K \).
- **A3.** If \( (A_i : i < \delta) \) is a continuous \( \prec_K \)-increasing chain:
  1. \( \bigcup_{i<\delta} A_i \in K \);
  2. for each \( j < \delta, A_j \prec_K \bigcup_{i<\delta} A_i \);
  3. if each \( A_i \prec_K M \in K \) then \( \bigcup_{i<\delta} A_i \prec_K M \).
Theorem

A4. If $A, B, C \in K$, $A \prec_K C$, $B \prec_K C$ and $A \subseteq B$ then $A \prec_K B$.

A5. There is a Löwenheim–Skolem number $\text{LS}(K)$ such that if $A \subseteq B \in K$ there is a $A' \in K$ with $A \subseteq A' \prec_K B$ and $|A'| \leq |A| + \text{LS}(K)$.

Here, $\langle A_i : i < \delta \rangle$ is a continuous $\prec_K$-increasing chain provided that $A_i \in K$ and $A_i \prec_K A_{i+1}$ for all $i < \delta$, and $A_i = \bigcup_{j < i} A_j$ for all limit ordinals $i < \delta$.

If $M \prec_K N$ we say that $M$ is a strong submodule of $N$. If $f : M \to N$ is 1-1 and $fM \prec_K N$, we call $f$ a strong embedding.

In what follows $R$ denotes a ring (= associative ring with unit) and $N$ a module (= unitary right $R$-module). When $A$ and $B$ are modules, $A \subseteq B$ means $A$ is a submodule of $B$.

**Definition 1.2.** The class $(\perp N, \prec_N)$ is defined by

$$\perp N = \{ A : \text{Ext}^i(A, N) = 0 \text{ for all } 1 \leq i < \omega \},$$

and $A \prec_N B$ if and only if $A \subseteq B$ and $A, B/A \in \perp N$.

It should be noted that the notation is not consistent in the literature. What we call $\perp N$ here is often (e.g. in [12]) denoted by $\perp \infty N$, while $\perp N$ refers to $\{ A : \text{Ext}^i(A, N) = 0 \}$. But we use $\perp N$ for the class that is most useful in our context. (For abelian groups, or more generally, for modules over right hereditary rings, the two notions coincide.)

Notice that, since $\text{Ext}^i(-, N)$ takes direct sums into direct products, the class $\perp N$ is closed under arbitrary direct sums. Moreover, it is *resolving*, that is, it contains all projective modules, is closed under extensions (i.e. whenever there is an exact sequence $0 \to X \to Y \to Z \to 0$ with $X, Z \in \perp N$ then $Y \in \perp N$) and has the property that $X \in \perp N$ whenever there is an exact sequence $0 \to X \to Y \to Z \to 0$ with $Y, Z \in \perp N$ (see [12, 2.2.9]).

The notion of $\perp N$ generalizes the concept of a Whitehead group: the class of all Whitehead groups is the special case for $R = N = \mathbb{Z}$. (The class $(1\mathbb{Z}, \prec_g)$ does not form an AEC; this follows from Theorem 0.1.(3), since $\mathbb{Z}$ is not a cotorsion abelian group; alternately, one can easily construct a counterexample to A.3(3), for example, one such that $M$ and $\bigcup_{i < \delta} A_i$ are free, each $A_i$ is finitely generated, and $M/\bigcup_{i < \delta} A_i \cong \mathbb{Q}$.)

The definition of $\perp N$ can be generalized to that of

$$\perp C = \{ A : \text{Ext}^i(A, N) = 0 \text{ for all } 1 \leq i < \omega \text{ and all } N \in C \}$$

where $C$ is a class of $R$-modules. This is often studied in the context of cotorsion pairs, that is, maximal pairs of Ext-orthogonal classes; see [12] and [10]. We will state at the end of this section a generalization of Theorem 0.1 for classes of the form $\perp C$.

A module $N$ is said to have *injective dimension* $\leq 1$ if $\text{Ext}^i(A, N) = 0$ for all $i > 1$ and all modules $A$. In this case of course $\perp N = \{ A : \text{Ext}^i(A, N) = 0 \} = 0$.

A pair of classes of modules $(C, D)$ is a *torsion pair* if $C = \{ M : \text{Hom}(M, D) = 0 \text{ for all } D \in D \}$ and $D = \{ N : \text{Hom}(C, N) = 0 \text{ for all } C \in C \}$. There is a torsion pair of the form $(C, D)$ if and only if $D$ is a torsion-free class of modules, that is, $D$ is closed under direct products, extensions and submodules.

If $N$ has injective dimension $\leq 1$ and $\perp N = \text{Cog}(N)$ where $\text{Cog}(N)$ is the class of all submodules of direct products of copies of $N$, then $N$ is called a cotilting module, and $\perp N$ the cotilting class induced by $N$. Each cotilting class is a torsion-free class of modules, so there is a torsion pair of the form $(T, \perp N)$, called the cotilting torsion pair induced by $N$. (Again, for simplicity of notation, we deviate here from the terminology of [12] where the term ‘1-cotilting module/class’ is used. We refer to [12, Chap. 8] for more on cotilting modules and classes.)

If all modules have injective dimension $\leq 1$, then $R$ is a *right hereditary ring*; hereditary integral domains are called *Dedekind domains*. Every Dedekind domain $R$ is (right) noetherian, that is, each (right) ideal of $R$ is finitely generated.

The notion of $\prec_N$ that we have chosen for our notion of a strong submodule arose in the module theory context in the guise of a $\mathcal{C}$-filtration. It was independently developed by the ‘Abelian group group’ of the AIM workshop on Abstract Elementary Classes in July 2006 [5].

**Definition 1.3.** Let $\mathcal{C}$ be a class of modules. A *$\mathcal{C}$-filtration* of a module $A$ is a continuous increasing chain $\langle A_i : i \leq \delta \rangle$ of its submodules such that $A_0 = 0$, $A = A_\delta$, and $A_{i+1}/A_i \in \mathcal{C}$ for each $i < \delta$. 
We begin the proof of Theorem 0.1 by checking that each axiom is satisfied for the class \((\downarrow N, \prec_N)\):

**A1** is trivial.

**A2** requires a small observation. We want to show \(A \prec_N B\) and \(B \prec_N C\) implies \(A \prec_N C\); that is, \(\text{Ext}^i(C/A, N) = 0\) for all \(i > 0\). We have an exact sequence:

\[
0 \to B/A \to C/A \to C/B \to 0.
\]

Applying \(\text{Hom}(-, N)\), we obtain the induced long exact sequence

\[
\cdots \to \text{Ext}^i(C/B, N) \to \text{Ext}^i(C/A, N) \to \text{Ext}^i(B/A, N) \to \cdots
\]

Since the outer terms are 0, so is the middle one, for each \(i > 0\).

**A3** is more complicated. First, we will show that \(A3(1)\) and \(A3(2)\) always hold. The key point here is ‘Eklof’s Lemma’ saying that each \(\downarrow N\)-filtered module is actually in \(\downarrow N\):

**Lemma 1.4.** Let \(A\) be a module. Suppose that \(A\) follows from \(\downarrow N\). Here, we mean closure under direct limits of well-ordered chains of homomorphisms. Let \(R\) be a ring and \(N\) a module. Then Theorem 0.1.

**Remark 1.6.**

**Lemma 1.5.** Suppose \(A = \bigcup_{\alpha < \mu} A_\alpha\) where \(\langle A_\alpha : \alpha < \mu \rangle\) is a continuous chain of modules with \(A_0 \in \downarrow N\) and for all \(\alpha < \mu\), \(A_{\alpha+1}/A_\alpha \in \downarrow N\). Then \(A \in \downarrow N\).

From this result, \(A3(1)\) is immediate. **Lemma 1.4** follows from \([10, \text{XII.1.5}]\); another proof is in \([12, \text{3.1.2}]\).

Next, we show that \(A3(2)\) follows from \(A3(1)\). Suppose \(\langle A_i : i < \delta \rangle\) is a \(\prec_N\) continuous increasing chain with union \(A\). We must show each \(A_i/A_j \in \downarrow N\). Note that \(A/A_i = \bigcup_{j \geq i} A_j/A_i\) so by \(A3(1)\) it suffices to show each \(A_i/A_j \in \downarrow N\) and each \(A_j/A_i \in \downarrow N\). The first follows from the definition of the chain and induction using transitivity and \(A3(1)\) for limit stages. The second requires that

\[
(A_{j+1}/A_i)/(A_j/A_i)
\]

be in \(N\). But this is isomorphic to \(A_{j+1}/A_j\) which is in \(\downarrow N\) by hypothesis.

**Condition A3(3),** however, is quite a strong one:

**Lemma 1.5.** Let \(R\) be a ring and \(N\) a module. Then \(A3(3)\) holds for the class \((\downarrow N, \prec_N)\) if and only if \(\downarrow N\) is closed under direct limits.

**Remark 1.6.** Here, we mean closure under direct limits of homomorphisms, not just direct limits of strong embeddings which is a well-known consequence of \(A3\) (Chapter 5 of \([4]\)). One could rephrase this lemma as: \(\downarrow N\) is closed under direct limits of ‘strong embeddings’ \((\prec_N\)-morphisms) if and only if \(\downarrow N\) is closed under direct limits of homomorphisms. We could have stated the condition as \(A3(3)\) since, as we have just seen, in this context \(A3(1)\) and \(A3(2)\) always hold.

**Proof.** First, assume that \(\downarrow N\) is closed under direct limits. To verify \(A3(3)\), suppose \(\langle A_i : i < \alpha \rangle\) is a \(\prec_N\) continuous increasing chain with union \(A\) and each \(A_i \prec_N B\). We must show \(B/A \in \downarrow N\). But \(B/A\) is the direct limit of the family of surjective homomorphisms \(f_{j,i} : B/A_i \to B/A_j\), for \(i \leq j\).

Conversely, assume \(A3(3)\) holds for the class \((\downarrow N, \prec_N)\). By \([1, \text{Corollary 1.7}]\), it suffices to prove that \(\downarrow N\) is closed under direct limits of well-ordered chains of homomorphisms. Let \(M = (M_\alpha, f_{\beta\alpha} : \alpha \leq \beta < \sigma)\) be such a chain with \(M_\alpha \in \downarrow N\) for all \(\alpha < \sigma\). (Though \(M\) is required here to be well ordered, the maps \(f_{\beta\alpha}\) are not assumed to be monic. Notice that \([1]\) uses category-theoretical rather than algebraic terminology: in \([1, \text{Corollary 1.7}]\), ‘direct limits’ are called ‘directed colimits’).

If \(\sigma\) is a nonlimit ordinal, then \(\lim M_\alpha = M_{\sigma-1} \in \downarrow N\) by assumption.

Assume \(\sigma\) is a limit ordinal. Consider the canonical presentation of \(M = \lim M_\alpha\)

\[
0 \to K \to A \to M \to 0
\]

where \(A = \bigoplus_{\alpha < \sigma} M_\alpha \in \downarrow N\) (since \(\downarrow N\) is closed under direct sums), and \(K\) is the submodule of \(A\) generated by all elements of the form \(x_{\beta\alpha} = m - f_{\beta\alpha}(m)\) where \(\alpha \leq \beta < \sigma\) and \(m \in M_\alpha\). Let \(K_\gamma\) denote the submodule of \(K\) generated only by the \(x_{\beta\alpha}\)’s with \(\beta < \gamma\). Then \((K_\gamma : 1 \leq \gamma \leq \sigma)\) is a continuous chain of submodules of \(A\), and \(K_0 = K\).

By induction on \(\gamma \leq \sigma\), we prove that \(K_\gamma \in \downarrow N\) and \(A/K_\gamma \in \downarrow N\). This is clear for \(K_1 = 0\). If \(\gamma\) is nonlimit, then \(K_\gamma + M_{\gamma-1} \supseteq \bigoplus_{\alpha < \gamma} M_\alpha\), hence \(A = K_\gamma \oplus L_\gamma\) where \(L_\gamma\) denotes the direct summand of \(A\) generated by all \(M_\alpha\)’s.
with $\gamma - 1 \leq \alpha < \sigma$. Since $A/K_\gamma \cong L_\gamma$ is a direct sum of members of $\perp N$, $A/K_\gamma \in \perp N$; then $K_\gamma \in \perp N$ since $\perp N$ is resolving.

Let $\gamma$ be a limit ordinal. By the inductive premise, $K_\delta \in \perp N$ and $A/K_\delta \in \perp N$ for each $\delta < \gamma$. Since $\perp N$ is resolving, we have also $K_{\delta+1}/K_\delta \in \perp N$, so $K_\gamma = \bigcup_{\delta<\gamma} K_\delta \in \perp N$ by A3(1), and $A/K_\gamma = A/\bigcup_{\delta<\gamma} K_\delta \in \perp N$ by A3(3).

In particular, for $\gamma = \sigma$, we obtain $M \cong A/K_\sigma \in \perp N$. □

At this point, pure-injective and cotorsion modules enter the scene. In Lemma 1.8, we will discuss their role for A3(3) in the general setting, but we will have a complete characterization only in the particular case of Dedekind domains (see Lemma 1.9).

The pure-injective modules are the same as the algebraically compact modules; see [10, Section V.1] for details. For $\mathbb{Z}$-modules (abelian groups) and, more generally modules over Dedekind domains, the cotorsion modules can be defined as the homomorphic images of pure-injective modules. Equivalently, for these rings they are the modules $N$ satisfying $\text{Ext}^1(J, N) = 0$ for every torsion-free module $J$, or just $\text{Ext}^1(Q, N) = 0$ (where $Q$ denotes the quotient field of the domain).

There is a structure theory for pure-injective modules over a Dedekind domain, but the class of all cotorsion modules over a Dedekind domain is quite complex. For example, any torsion module $T$ occurs as the torsion part of a cotorsion module (namely, of $\text{Ext}^1(Q/R, T)$). However, the torsion-free cotorsion modules are fully understood: they are the pure-injective torsion-free modules, that is, they are the direct sums of copies of $Q$ plus direct products, over all maximal ideals $p$, of completions of free $R_p$-modules where $R_p$ denotes the localization of $R$ at $p$.

A module $J$ over a ring $R$ is flat if and only if $J$ is a direct limit of (finitely generated) projective modules. For modules over a Dedekind domain, the flat modules are precisely the torsion-free modules, because, in that case, a finitely generated module is projective if and only if it is torsion free.

**Definition 1.7.** A module $N$ over a ring $R$ is cotorsion if $\text{Ext}^1(J, N) = 0$ for every flat module $J$.

**Lemma 1.8.** Let $R$ be a ring and $N$ a module. If A3(3) holds for the class $(\perp N, \prec_N)$ then $N$ is cotorsion.

Conversely, if $N$ is pure injective then $\perp N$ is closed under direct limits, so by Lemma 1.5, the class $(\perp N, \prec_N)$ satisfies A3(3).

**Proof.** If A3(3) holds for the class $(\perp N, \prec_N)$ then $\perp N$ is closed under direct limits by Lemma 1.5. Since $\perp N$ always contains all projective modules, it contains also all flat modules, so $N$ is cotorsion.

For the second part, note first that it suffices to show $\perp N$ is closed under homomorphic images of pure epimorphisms because the canonical map of a direct sum onto a direct limit is a pure epimorphism. As in the proof of [11, Lemma 9] we can show that $\{A : \text{Ext}^1(A, N) = 0\}$ is closed under homomorphic images of pure epimorphisms for each pure-injective $N$. By [12, 3.2.10], for each $i > 0$ there is a pure-injective module $N_i$ such that $\text{Ext}^1(A, N_i) \cong \text{Ext}^1(A, N_i)$ for all modules $A$. Thus also $\perp N$ is closed under homomorphic images of pure epimorphisms, and thus under direct limits. □

There is still a gap between the two parts of Lemma 1.8; we do not know exactly the rings for which the hypothesis of $N$ cotorsion is sufficient for A3(3). It is sufficient when $R$ is a Dedekind domain:

**Lemma 1.9.** Let $R$ be a Dedekind domain and $N$ a module. Then the following are equivalent:

(1) $N$ is cotorsion;
(2) $\perp N = \perp PE(N)$ where $PE(N)$ denotes the pure-injective envelope of $N$;
(3) $\perp N$ is closed under direct limits;
(4) A3(3) holds for $(\perp N, \prec_N)$.

**Proof.** (1) implies (2) by [11, Theorem 16 (ii)(b)]. (2) implies (3) by the second part of Lemma 1.8, and (3) is equivalent to (4) by Lemma 1.5. Finally, (4) implies (1) by the first part of Lemma 1.8. □

Now, we return to the open problem of characterizing A3(3) in the general setting. The reader who is interested mainly in the case of abelian groups, or modules over Dedekind domains, can skip this part and proceed directly to Lemma 1.14.
**Lemma 1.10.** Assume that $R$ is a right noetherian ring and the module $N$ has injective dimension $\leq 1$. Then the conditions (2), (3) and (4) of Lemma 1.9 are equivalent.

**Proof.** First, we claim that for any finitely generated module $F$, the condition $\Ext^1(F, X) = 0$ is a first order property of $X$. Indeed, let $0 \to G \subseteq R^n \to F \to 0$ be a presentation of $F$ where $m$ is finite. Then $\Ext^1(F, N) = 0$ just says that any $R$-homomorphism $g : G \to N$ can be extended to an $R$-homomorphism $f : R^n \to N$.

By the hypothesis on $R$, $G$ is finitely generated. Let $(g_1, \ldots, g_n) \in R^m$ for each $j \leq n$. Let $0 \to H \subseteq R^n \to G \to 0$ be the presentation of $G$ with $\pi(1_j) = g_j$ ($j \leq n$). Let $(h_1, \ldots, h_p)$ be a finite $R$-generating subset of $H$. Let $\{h_1, \ldots, h_p\} \in R^m$ be a finite $R$-generating subset of $H$, $h_k = (h_{k1}, \ldots, h_{kn}) \in R^m$ ($k \leq p$).

Then $g : G \to N$ is uniquely determined by an $n$-tuple $(x_1, \ldots, x_n)$ of elements of $N$ satisfying $\sum_{j \leq n} x_j h_{kj} = 0$ for each $k \leq p$. Similarly, $f : R^n \to N$ is uniquely determined by an $m$-tuple $(y_1, \ldots, y_m)$ of elements of $N$. Finally, $f$ extends $g$ if and only if $\sum_{j \leq m} y_j g_{ji} = x_j$ for each $j \leq n$. This finishes the proof of our claim.

Notice that for any module $N$, the modules $N$ and $PE(N)$ are elementarily equivalent. Since $R$ is right noetherian, syzygies of finitely generated modules can be taken finitely generated. So our claim and the Baer test of injectivity imply that the injective dimensions of $N$ and $PE(N)$ coincide, hence they are $\leq 1$. So the classes $\perp N$ and $\perp PE(N)$ are closed under submodules, and again by our claim, they contain the same finitely generated modules.

By Lemmas 1.5 and 1.8, we only have to prove that (3) implies (2). By (3) and the fact that $N$ has injective dimension $\leq 1$, we have $M \in \perp N$ iff all finitely generated submodules of $M$ are in $\perp N$. Similarly, by the second part of Lemma 1.8, we have $M \in \perp PE(N)$ iff all finitely generated submodules of $M$ are in $\perp PE(N)$. However, we have just seen that a finitely generated module belongs to $\perp N$ if and only if it belongs to $\perp PE(N)$. $\square$

In general, condition (1) of Lemma 1.9 does not imply A3(3) for $(\perp N, \prec_N)$. We will see this in the next example, which is expounded from here until Lemma 1.14.

Recall that a ring $R$ is right artinian if $R$ has d.c.c. on right ideals. Equivalently, $R$ is right noetherian and each flat module is projective. In particular, every module over a right artinian ring is cotorsion, so condition (1) is vacuous (satisfied for each $N$).

Note that right artinian rings and Dedekind domains share the property that each finitely generated module is a direct sum of a projective module and an artinian module (i.e. one that satisfies d.c.c. on submodules). This is the property needed in the next lemma.

**Lemma 1.11.** Let be $R$ a right noetherian ring such that each finitely generated module is a direct sum of a projective module and an artinian module. Let $N$ be a module of injective dimension $\leq 1$ such that $\perp N$ is closed under direct limits. Then $\perp N$ is a torsion-free class of modules.

**Proof.** We modify the proof of Theorem [12, 8.2.17(b), p. 291] as follows:

Denote by $\mathcal{F}$ the class of all finitely generated modules in $\perp N$. By assumption, if $M$ is an arbitrarily finitely generated module, then $M = F \oplus Q$ where $F$ is projective and $Q$ is artinian. Let $\mathcal{P} = \{P \subseteq M : M/P \in \mathcal{F}\}$. Then $\mathcal{P}$ is closed under finite intersections because $\mathcal{F}$ is closed under submodules and finite direct products. So $P(M) = \bigcap_{P \in \mathcal{P}} P \subseteq Q$ is the smallest submodule of $M$ such that $M/P(M) \in \mathcal{F}$ (because $F \in \perp N$ and $Q$ is artinian). As in [12, 8.2.17(b)], we see that $(T, \mathcal{F})$ is a torsion pair in the category of all finitely generated modules where $T$ denotes the class of all finitely generated modules $T$ such that $\Hom_R(T, F) = 0$ for all $F \in \mathcal{F}$.

By [12, 4.5.2(b)], $(\lim T, \lim \mathcal{F})$ is a torsion pair in the category of all modules. By assumption, $\perp N$ is closed under direct limits, so $\perp N \supseteq \lim \mathcal{F}$. Since $R$ is right noetherian and $\perp N$ is closed under submodules, also $\perp N \subseteq \lim \mathcal{F}$. This proves that $\perp N = \lim \mathcal{F}$ is a torsion-free class of modules. $\square$

The following lemma will be helpful in constructing the example:

**Lemma 1.12.** Let $R$ be as in Lemma 1.11. Let $N$ be a module of injective dimension $\leq 1$ such that $\Ext^1(N, N) = 0$ and A3(3) holds for $(\perp N, \prec_N)$. Then $N$ is pure injective.

In particular, if $R$ is a Dedekind domain and $N$ is a module such that $\Ext^1(N, N) = 0$, then $N$ is cotorsion iff $N$ is pure injective.

**Proof.** By Lemmas 1.5 and 1.11, and by [12, 8.2.4], $\perp N$ is a cotilting class of modules, that is, there is a cotilting module $C$ such that $\perp N = \perp C$. By [12, 8.1.7], each cotilting module is pure injective. Moreover, by [12, 8.1.4(c)], all
modules in the subclass $S = \{ B \in \perp C : \text{Ext}^i(A, B) = 0 \text{ for all } 1 \leq i < \omega \text{ and all } A \in \perp C \}$ are direct summands of direct products of copies of $C$; in particular, they are also pure injective. However, our assumption of $\text{Ext}^i(N, N) = 0$ implies $N \in S$.

If $R$ is a Dedekind domain and $N$ is cotorsion then $A3(3)$ holds by Lemma 1.9, so $N$ is pure injective by the argument above. □

**Example 1.13.** We will show that $A.3(3)$ fails for $(\perp N, \prec N)$ for certain (cotorsion) modules over rings which are (right) hereditary, artinian and countable. We refer to [3] for more details on this example. Let $R$ be a tame hereditary finite-dimensional algebra over a field $k$. (Note that $R$ is countable when $k$ is.)

If $N$ is a finite-dimensional module, then $N$ is endofinite, hence pure injective, so $\perp N$ is closed under direct limits by Lemma 1.8, and $(\perp N, \prec N)$ satisfies $A3(3)$.

By Lemma 1.12, for the desired example it suffices to take any infinite-dimensional tilting module $N$ which is not pure injective. We claim that the (countable dimensional) Lukas tilting module $N$ from [12, 5.1.5(b)] has this property. Indeed, $\perp N$ is the class of all Baer modules, which is not closed under direct limits (it contains neither the generic module nor the product of all indecomposable preprojective modules, see [3]), and Lemma 1.8 applies.

A4 is rather straightforward.

**Lemma 1.14.** If $R$ is any ring and $N$ any module then $A4$ holds for $(\perp N, \prec N)$.

**Proof.** Suppose $A \subseteq B \subseteq C$ with $A \prec N C$ and $B \prec N C$. To show $A \prec N B$, we need only show $B/A \in \perp N$. But this is immediate from the resolving property of $\perp N$ applied to the exact sequence $0 \to B/A \to C/A \to C/B \to 0$. □

The verification of $A5$ relies on the following notion; we modify the notation in [11].

**Definition 1.15.** For any right $R$-module $A$ and any cardinal $\kappa$, a $(\kappa, N)$-refinement of length $\sigma$ of $A$ is a continuous chain $(A_{\alpha} : \alpha < \sigma)$ of submodules such that $A_0 = 0$, $A_{\alpha+1}/A_{\alpha} \in \perp N$, and $|A_{\alpha+1}/A_{\alpha}| \leq \kappa$ for all $\alpha < \sigma$.

We state now a version of Theorem 6 of [22] (see also [12, 4.2.6]) where we omit some of the conclusions not needed here.

**Lemma 1.16 (Hill’s Lemma).** Let $\kappa$ be a regular infinite cardinal. Suppose $M$ admits a $C$-filtration $(M_{\alpha} : \alpha \leq \sigma)$, where $C$ is a set of $< \kappa$-presented modules. Then there is a family $\mathcal{F}$ of submodules of $M = M_\sigma$ such that:

1. $M_{\alpha} \in \mathcal{F}$ for all $\alpha \leq \sigma$.
2. $\mathcal{F}$ is closed under arbitrary intersections and sums.
3. Let $N \subseteq P$ both be in $\mathcal{F}$. Then $P/N$ has a $C$-filtration.
4. If $N \in \mathcal{F}$ and $X \subseteq M$ with $|X| < \kappa$, then there is a $P \in \mathcal{F}$ with $N \subseteq P$ and $P/N \prec \kappa$ presented.

**Lemma 1.17.** Let $\kappa$ be a cardinal $\geq |R| + \aleph_0$. Let $N$ be a module.

1. If every module $A \in \perp N$ has a $(\kappa, N)$-refinement then $(\perp N, \prec N)$ has Löwenheim-Skolem number $\kappa$.
2. If $(\perp N, \prec N)$ has Löwenheim-Skolem number $\kappa$ and satisfies $A3(3)$ then every module $A \in \perp N$ has a $(\kappa, N)$-refinement.

**Proof.** Since $\kappa \geq |R| + \aleph_0$, a $(\kappa, N)$-refinement of a module $M$ yields a $C$-filtration of $M$ where $C$ is the class of all $\leq \kappa$-presented elements of $\perp N$. We use Lemma 1.16 for $\kappa^+$. If $A \in \mathcal{F}$, then by Eklolf’s Lemma and (3) of Lemma 1.16, $A \prec N M$. Write an arbitrary $X \subseteq M$ as $\bigcup_{i < \mu} X_i$ where $|X_i| \leq \kappa$ and $\mu = |X|$. Then inductively, using condition (4), we select from $\mathcal{F}$ a continuous chain of submodules of $M$, $\langle N_i : i \leq \mu \rangle$, so that

1. $N_0 = 0$;
2. $N_{i+1} \supseteq N_i \cup X_i$;
3. $N_{i+1}/N_i$ is $\leq \kappa$-presented.

Then $N_\mu$ is as required.

Conversely, assume $(\perp N, \prec N)$ has Löwenheim-Skolem number $\kappa$. Let $A \in \perp N$ and let $X$ be a set of $R$-generators of $A$. A $(\kappa, N)$-refinement $\langle A_{\alpha} : \alpha < \sigma \rangle$ of $A$ consisting of strong submodules of $A$ is constructed by induction as follows:
A_0 = 0, and if A_α is defined and there is x ∈ A \ A_α then applying A_5 to A/A_α yields a submodule A_{α+1} containing A_α + x R and such that A_{α+1}/A_α ∈ ⊥^N, A/A_{α+1} ∈ ⊥^N and |A_{α+1}/A_α| ≤ |(A_α + x R)/A_α| + κ. Since (A_α + x R)/A_α ≃ x R/(A_α ∩ x R), also |(A_α + x R)/A_α| ≤ κ, hence |A_{α+1}/A_α| ≤ κ. The resolving property of ⊥^N gives A_{α+1} ∈ ⊥^N.

For a limit ordinal α we define A_α = ∪_β<α A_β, so A_α ∈ ⊥^N by A_3(1), and A/A_α ∈ ⊥^N by A_3(3).

**Remark 1.18 (Summary).** We have shown that (⊥^N, ≺_N) is an AEC if and only if ⊥^N has (κ, N)-refinements for some κ and is closed under direct limits of homomorphisms.

But the question of when refinements exist is rather complicated.

**Lemma 1.19.** Each member of ⊥^N admits a (κ, N)-refinement under any of the following conditions:

1. N is pure injective and R is arbitrary; κ = |R| + ℵ_0.
2. N is cotorsion and R is a Dedekind domain; κ = |R| + ℵ_0.
3. (V = L) N is arbitrary and R is hereditary; κ = max{|R|, |N|} + ℵ_0.

**Proof.** These results are in [11]. (1) follows by Theorem 8; (3) is Theorem 14. (2) follows from (1) by Lemma 1.19.

Now, we just combine the results obtained above for a *Proof of Theorem 0.1*

Part (1) follows by Lemmas 1.8, 1.14 and 1.17(1), and 1.19(1).

Part (2) is by Lemmas 1.5 and 1.10, and Part (1).

Part (3) follows by Part (2) and Lemma 1.19.

**Theorem 0.1** can be generalized as follows: the proof is a straightforward generalization, where A ≺_C B means that B/A ∈ ⊥^C:

**Theorem 1.20.** (1) Let R be a ring and C a class of R-modules. If every module in C is pure injective, then the class (⊥^C, ≺_C) is an AEC. Conversely, if (⊥^C, ≺_C) is an AEC then every module in C is a cotorsion module.

(2) Let R be a right noetherian ring and C be a class of R-modules of injective dimension ≤ 1. Then the class (⊥^C, ≺_C) is an AEC if and only if ⊥^C is closed under direct limits.

(3) If R is a Dedekind domain and C is a class of R-modules, the class (⊥^C, ≺_C) is an AEC if and only if every member of C is cotorsion.

Here are some open questions:

**Question 1.21.** (1) Can the question of whether a class is an AEC (e.g. (⊥^N, ≺_N) for R hereditary) be independent of ZFC?

(2) Can the question of whether a class (e.g. Whitehead groups) is a PCI-class (defined as the reducts of models of say a countable theory omitting a family of types) be independent of ZFC? (Note that under V = L, ‘Whitehead=free’ and the class is easily PCI.)

(3) Characterize the cotorsion modules N over a ring R such that (⊥^N, ≺_N) is an AEC.

2. Amalgamation, closures, and stability

Recent studies in AEC [20,15,14,4,8] have focused on those AEC having additional properties such as amalgamation, tameness and admitting closures. Having established that (⊥^N, ≺_N) is an AEC for a number of N, we turn to establishing such model theoretical properties of the AEC.

In this section we show that for any N, (⊥^N, ≺_N) has the amalgamation property, and if N has injective dimension ≤ 1 then (⊥^N, ≺_N) admits intersections iff ⊥^N is a cotilting class. We will also show that the latter always holds when R is a Dedekind domain, and describe the closures explicitly in this case.

Note that for any N, all projective and in particular all free R-modules are in ⊥^N so (⊥^N, ≺_N) always has arbitrarily large models.

Now we show the first part of Theorem 0.2:
Lemma 2.1. \((\downarrow N, \prec_N)\) has the amalgamation property.

Proof. We just check if \(C \prec_N B \text{ and } C \prec_N A\) then the pushout \(D\) of \(A\) and \(B\) over \(C\) is in \(\downarrow N\) and \(B \prec_N C, A \prec_N D\). Consider the short exact sequence:

\[
0 \to C \to B \to B/C \to 0.
\]

By the universal mapping property of pushouts we get the diagram

\[
\begin{array}{ccc}
0 & \to & A \\
\uparrow & & \uparrow \\
0 & \to & C \\
\end{array}
\]

Then from the long exact sequence of Ext, we obtain the exact sequence

\[
\text{Ext}^1(B/C, N) \to \text{Ext}^1(D, N) \to \text{Ext}^1(A, N).
\]

But the first and last entries are 0, so \(D \in \downarrow N\). Now the commutative diagram shows \(D/A \cong B/C\) so \(A \prec_N D\). Performing the same construction starting with 0 \(\to C \to A \to A/C \to 0\), shows \(B \prec_N D\) and we finish. \(\square\)

Remark 2.2. It is easy to see that in the preceding construction, there is a copy of \(D\) over \(A\) in which \(A\) intersects the image of \(B\) in \(C\). Thus our classes have the ‘disjoint amalgamation property’.

Note that the argument for amalgamation also yields that each \((\downarrow N, \prec_N)\) has the ‘joint embedding property’ (any two members can be strongly embedded into some model). As with any AEC with the amalgamation property and joint embedding, we can now see:

Remark 2.3 (Conclusions). If \((\downarrow N, \prec_N)\) is an AEC, then

1. \((\downarrow N, \prec_N)\) has a monster model \(\mathbb{M}\) in the usual sense of AEC, (see [4]) (i.e. homogeneous over strong submodels).
2. \((\downarrow N, \prec_N)\) has EM-models and models generated by indiscernibles.

To study stability, we must define it. And for this we must introduce the notion of type that is appropriate here. We will use the monster model in our discussion of Galois types.

Definition 2.4. Let \((K, \prec_K)\) be an AEC with the amalgamation property and joint embedding.

1. For triples \((M, a, N)\) with \(M \prec_K N \in K\) and \(a \in N - M\), define

\[(M, a, N) \cong (M, a', N')\]

if there exists \(N''\) and strong embeddings \(f, f'\) taking \(N, N'\) into \(N''\) which agree on \(M\) and with

\[f(a) = f'(a').\]

2. ‘The Galois type of \(a\) over \(M\) in \(N\)’ is the same as ‘the Galois type of \(a'\) over \(M\) in \(N''\) if \((M, a, N)\) and \((M, a', N')\) are in the same class of the equivalence relation generated by \(\cong\).

3. We write \(\text{tp}(a/M)\) for the Galois type of \(a\) over \(M\). This can be thought of as either:

   (a) the equivalence class of \((M, a, \mathbb{M})\);
   (b) the orbit of \(a\) under \(\text{aut}_M(\mathbb{M})\).

4. Let \(M \subseteq N \subseteq \mathbb{M}\) and \(a \in \mathbb{M}\). The restriction of \(\text{tp}(a/N)\) to \(M\), denoted \(\text{tp}(a/N) \upharpoonright M\) is the orbit of \(a\) under \(\text{aut}_M(\mathbb{M})\).

5. \(ga - \text{S}(M)\) denotes the collection of Galois types over \(M\).

6. \((K, \prec_K)\) is \(\lambda\)-stable if for every \(M\) with \(|M| = \lambda\), \(|ga - \text{S}(M)| = \lambda\).

The definition of restriction makes sense since our classes have a monster model. Note that the definition of Galois type in 1) and 2) makes sense without an amalgamation assumption (but ‘generation’ in 2) means transitive closure of the given relation). With amalgamation we get the simpler relation of 3).

The analysis of Galois types in our situation relies on a definition from [8].
**Definition 2.5.** We say the AEC \( (K, \prec_K) \) admits intersections if for every \( X \subseteq M \in K \), there is a minimal closure of \( X \) in \( M \). That is, the structure with universe \( \bigcap \{ N : X \subseteq N \prec_K M \} \) is a strong submodel of \( M \). If so, we denote it: \( \text{cl}_M(X) \).

In our particular setting, the existence of closures translates into \( \bot N \) being a cotilting class. To see this, we first show that the existence of closures for modules in \( \bot N \) implies the existence of closures for arbitrary modules. We will start by allowing the relation \( \prec_N \) to hold between arbitrary modules instead of just members of \( \bot N \).

**Definition 2.6.** If \( A \) and \( B \) are arbitrary modules, we will say that \( A <_N B \) iff \( B/A \in \bot N \).

Notice that if \( A <_N B \) then \( A \in \bot N \) iff \( B \in \bot N \) since \( \bot N \) is resolving.

**Lemma 2.7.** Assume that \( (\bot N, <_N) \) is an AEC that admits intersections. Let \( X \) be a subset of a module \( M \) and let \( \mathcal{Q}^* = \bigcap \{ Q : X \subseteq Q <_N M \} \). Then \( \mathcal{Q}^* <_N M \).

**Proof.** Fix an epimorphism \( \pi : F \to M \) where \( F \) is a free module. For each submodule \( Q \) of \( M \), denote by \( \mu_Q : Q \to M \) the inclusion, and consider the pullback of \( \pi \) and \( \mu_Q \):

\[
\begin{array}{cccccc}
0 & \longrightarrow & P_Q & \xrightarrow{v_Q} & F & \longrightarrow & M/Q & \longrightarrow & 0 \\
\downarrow & & & & \downarrow & & & & \downarrow \\
0 & \longrightarrow & Q & \xrightarrow{\mu_Q} & M & \longrightarrow & M/Q & \longrightarrow & 0
\end{array}
\]

Notice that \( P_Q \) is just the set of all pairs \( (m, f) \in M \oplus F \) where \( m \in Q \) and \( \pi(f) = m \), and \( v_Q \) is the (injective) restriction to \( P_Q \) of the projection \( M \oplus F \to F \). Moreover, if \( Q <_N M \) then \( F, M/Q \in \bot N \), so \( P_Q \in \bot N \) since \( \bot N \) is resolving, and \( v_Q(P_Q) \to F \).

Let \( \mathcal{Q} = \{ Q : X \subseteq Q <_N M \} \). Notice that \( v_Q(P_Q) \subseteq \bigcap \{ \nu_Q(Q) : Q \in \mathcal{Q} \} \): the inclusion \( \subseteq \) is obvious, and if \( f \in \bigcap \{ \nu_Q(Q) : Q \in \mathcal{Q} \} \) then \( \pi(f) \in \mathcal{Q}^* \) so \( f \in v_Q(P_Q) \). Since \( (\bot N, <_N) \) admits intersections, \( v_Q(P_Q) \) is a strong submodule of \( F \). But, by the last paragraph, this implies \( M/Q^* \in \bot N \), that is, \( \mathcal{Q}^* <_N M \). \( \square \)

**Lemma 2.8.** Let \( R \) be a ring, and \( N \) be a module of injective dimension \( \leq 1 \). Then the following conditions are equivalent:

1. \( (\bot N, <_N) \) is an AEC that admits intersections;
2. \( \bot N \) is closed under direct products;
3. \( \bot N \) is a cotilting class.

These conditions imply that \( \bot N \) is first order axiomatizable and moreover, the closure, \( \text{cl}_M(X) \), is determined by \( \text{cl}_M(X)/X \) being the \( T \)-torsion part of \( M/X \) where \( (T, \bot N) \) is the induced cotilting torsion pair.

**Proof.** The implication (1) \( \implies \) (2) holds for any module \( N \):

Assume that (1) holds and there are a cardinal \( \kappa \) and modules \( M_\alpha \in \bot N (\alpha < \kappa) \) such that \( P = \prod_{\alpha < \kappa} M_\alpha \notin \bot N \).

We take \( \kappa \) the smallest possible; notice that \( \kappa \) is infinite since \( \bot N \) is closed under direct sums. For each \( \alpha < \kappa \), let \( P_\alpha = \{ p \in P : p_\beta = 0 \text{ for all } \beta < \alpha \} \). Then \( P/P_\alpha \cong \prod_{\beta < \alpha} M_\beta \in \bot N \) by the minimality of \( \kappa \), so \( P_\alpha <_N P \).

**Lemma 2.7** implies that \( \bigcap_{\alpha < \kappa} P_\alpha \notin \bot N \). But \( \bigcap_{\alpha < \kappa} P_\alpha = 0 \), so \( P/\bigcap_{\alpha < \kappa} P_\alpha \cong P \in \bot N \), a contradiction.

(2) \implies (3) by [12, 8.1.10].

Assume (3). Since any cotilting class is of the form \( \bot N \) for a cotilting module \( N \), and \( N \) is pure injective by [12, 8.1.7], \( (\bot N, <_N) \) is an AEC by Theorem 0.1(1).

Let \( X \subseteq M \in \bot N \). Let \( \mathcal{Q}^* = \bigcap \{ Q : X \subseteq Q <_N M \} \). Then the map \( \varphi : M/Q^* \to \prod_{X \subseteq Q <_N M} M/Q \) assigning to each \( m+Q \) the sequence \( (m+Q)_{X \subseteq Q <_N M} \) is monic. Since \( \bot N \) is a cotilting class, it is closed under direct products and submodules, so \( \prod_{X \subseteq Q <_N M} M/Q \in \bot N \), and \( M/Q^* \in \bot N \). As \( \bot N \) is resolving, we conclude that \( \mathcal{Q}^* \) is a strong submodule of \( M \), so \( (\bot N, <_N) \) admits intersections.

Finally, any cotilting class is ‘definable’ (that is, closed under direct products, direct limits and pure submodules), so it is axiomatizable (by axioms saying that certain of the Baur–Garavaglia–Monk invariants are equal to 1), cf. [9, 2.3] and [18, p.34].
Moreover, since \((T, \perp_N)\) is a torsion pair, we have \(M/Y \cong (M/X)/(Y/X) \in \perp_N\) where \(Y/X\) is the \(T\)-torsion part of \(M/X\), and if \(X \subseteq P \prec_N M\) then \(Y \subseteq P\) since otherwise (\(Y/X)/(P/X \cap Y/X) \cong (P/X + Y/X)/(P/X) \cong (P + Y)/P\) is isomorphic to a nonzero \(T\)-torsion submodule of \(M/P \in \perp_N\). This proves that \(\text{cl}_M(X) = Y/X\). \(\square\)

Our main applications are to abelian groups, or, more generally, modules over Dedekind domains, so we note that in that case the AEC \((\perp_N, \prec_N)\) always admits intersections, that is, \(\perp_N\) is a cotilting class. Moreover, we provide an explicit construction of the closures.

Recall that for a set of maximal ideals \(P\), \(K(P)\) is defined as the class of all modules that are \(p\)-torsion-free for all \(p \in P\).

**Lemma 2.9.** Let \(R\) be a Dedekind domain. If \((\perp_N, \prec_N)\) is an AEC, then \(\perp_N\) coincides with the (first order axiomatizable) class \(K(P)\) for a set \(P\) of maximal ideals of \(R\) and \((\perp_N, \prec_N)\) admits intersections. The closure \(\text{cl}_M(X)\) coincides with the submodule of \(M\) consisting of all \(m \in M\) such that the ideal \(\{r \in R : mr \in X\}\) is a finite product of elements of \(P\).

Conversely, for any set of maximal ideals \(P\), there is a pure-injective module \(N\) such that \((\perp_N, \prec_N)\) is an AEC such that \(\perp_N = K(P)\).

**Proof.** For the first claim, let \(P\) be the set of all maximal ideals \(p\) of \(R\) such that \(R/p \not\in \perp_N\). Then \(\perp_N = K(P)\) by [11, Theorem 16(i)]. For the second claim, it suffices, by Lemma 2.8, to show that \(K(P)\) is closed under direct products; but this is obvious from the definition of \(K(P)\).

By Lemma 2.8, \(\text{cl}_M(X)/X\) coincides with the \(T\)-torsion part of \(M/X\) where \((T, \perp_N)\) is the cotilting torsion pair. By [12, 8.2.11], this torsion pair is hereditary in the sense of [21, VI, Section 3], that is, there is a Gabriel topology (filter) \(\mathfrak{F}\) of ideals of \(R\) such that for each module \(N\), \(N \in T\) iff each element from \(N\) is annihilated by an element of \(\mathfrak{F}\). Since each nonzero ideal of \(R\) is uniquely a finite product of prime ideals (see [17, Theorem 11.6]), and \(\perp_N = K(P)\), we infer that \(\mathfrak{F}\) coincides with the set of all ideals of \(R\) which are finite products of elements of \(P\) (here we include \(R\) as the ‘empty’ case of such product). In particular, the \(T\)-torsion part of \(M/X\) consists of all elements \(m \in M\) such that \(\{r \in R : mr \in X\}\) is a finite product of prime ideals from \(P\).

Conversely, for any set of maximal ideals \(P\), \(K(P)\) is closed under direct products; but this is obvious from the definition of \(K(P)\).

By Lemma 2.8, \(\text{cl}_M(X)/X\) coincides with the \(T\)-torsion part of \(M/X\) where \((T, \perp_N)\) is the cotilting torsion pair. By [12, 8.2.11], this torsion pair is hereditary in the sense of [21, VI, Section 3], that is, there is a Gabriel topology (filter) \(\mathfrak{F}\) of ideals of \(R\) such that for each module \(N\), \(N \in T\) iff each element from \(N\) is annihilated by an element of \(\mathfrak{F}\). Since each nonzero ideal of \(R\) is uniquely a finite product of prime ideals (see [17, Theorem 11.6]), and \(\perp_N = K(P)\), we infer that \(\mathfrak{F}\) coincides with the set of all ideals of \(R\) which are finite products of elements of \(P\) (here we include \(R\) as the ‘empty’ case of such product). In particular, the \(T\)-torsion part of \(M/X\) consists of all elements \(m \in M\) such that \(\{r \in R : mr \in X\}\) is a finite product of prime ideals from \(P\).

Finally, we prove that \(K(P)\) is first order axiomatizable for any set of maximal ideals \(P\). For each \(p \in P\), let \(\{a_{p,1}, \ldots, a_{p,k_p}\}\) be a finite \(R\)-generating subset of \(p\). The first-order theory \(T_P\) which asserts that for all \(p \in P\) the simple module \(R/p\) does not embed into \(N\) just consists of the implications \((x.a_{p,1} = \cdots = x.a_{p,k_p} = 0) \rightarrow x = 0\) where \(p\) runs over all ideals in \(P\). \(\square\)

Parts (2) and (3) of Theorem 0.2 now follow immediately from Lemmas 2.8 and 2.9, respectively.

**Remark 2.10.** (i) The class \(\perp_N = K(P)\) above is elementary, but the unusual definition of \(\prec_N\) yields some new phenomena: we require that \(A \prec_N B\) iff \(B / A \models T_P\). This distinction was reflected for example in Lemma 2.7. While, by definition of cotilting, if \(N\) is cotilting some submodule \(A\) of a member \(B\) of \(\perp_N\) is in \(\perp_N\) if \(A \prec_N B\) may fail. In [8] an AEC \(K\) is called model complete if \(A \subseteq B\) and \(A, B \in K\) implies \(A \prec_K B\). Here we have natural examples where this condition fails: just consider a nonpure subgroup \(A\) of a torsion-free group \(B\).

(ii) The equivalence (2) \(\leftrightarrow\) (3) in Lemma 2.8 extends to any module \(N\) of injective dimension \(n < \omega\) if we replace ‘cotilting class’ by ‘\(n\)-cotilting class’ in the sense of [12, Chapter 8].

(iii) That \((\perp_N, \prec_N)\) admits intersections whenever \((\perp_N, \prec_N)\) is an AEC holds for any right noetherian ring whose finitely generated modules decompose into direct sums of projective and artinian modules, and any module \(N\) of injective dimension \(\leq 1\).

Notice that there exist rings \(R\) and AECs of the form \((\perp_N, \prec_N)\) that do not admit intersections:

**Example 2.11.** Consider any ring \(R\) which is right perfect (that is, all flat modules are projective), but not left perfect (see [2, p.322]). Then \(R\) is not left coherent (that is, there exists a finitely generated left ideal which is not finitely presented, see e.g. [18, 14.23]). Let \(N\) be the direct sum of a representative set of all simple modules. By [12, 4.1.8], \(\perp_N\) is the class of all projective modules (and \(\prec_N\) is the relation of being a direct summand). Since \(\perp_N = \perp_C\) where \(C\) is the class of all pure-injective modules (see [12, 2.2.3]), Theorem 1.20(1) implies that \((\perp_N, \prec_N)\) is an AEC.
But $R$ is not left coherent, so the class of all flat ($\Rightarrow$ projective) modules is not closed under direct products by a classical result of Chase [2, 19.20]. Hence $(\perp N, \preccurlyeq_N)$ does not admit intersections by (the implication (1) $\Rightarrow$ (2) of) Lemma 2.8.

We conclude this section by describing some general properties of Galois types. In Section 3, we will use these concepts to study the stability of $(\perp N, \preccurlyeq_N)$ for abelian groups $N$.

If $(K, \preccurlyeq_K)$ admits intersections then we have the following check (from [8]) for equality of Galois types. The relevance of the second clause is that even in the absence of amalgamation it shows that equality of Galois types is determined by the basic relation of Definition 2.4, rather than its transitive closure. By $M_1 \restriction \cl_{M_1}(M_0a_1)$ we simply mean the structure $M_1$ induces on the minimal $K$ substructure containing $M_0a_1$.

**Lemma 2.12.** Let $(K, \preccurlyeq_K)$ admit intersections:

1. Suppose $M_0 \preccurlyeq_K M_1, M_2$ with $a_i \in M_i$ for $i = 1, 2$. Then $tp(a_1/M_0, M_1) = tp(a_2/M_0, M_2)$ if and only if there is an isomorphism over $M_0$ from $M_1 \restriction \cl_{M_1}(M_0a_1)$ onto $M_2 \restriction \cl_{M_2}(M_0a_2)$ which maps $a_1$ to $a_2$.
2. $(M_1, a_1, N_1)$ and $(M_2, a_2, N_2)$ represent the same Galois type over $M_1$ iff $M_1 = M_2$ and there is an amalgam of $N_1$ and $N_2$ over $M_1$ where $a_1$ and $a_2$ have the same image.

The syntactic type of an element $a$ over a set $A$ is the set of formulas $\phi(x)$ in some logic with parameters from $A$ that are satisfied by $a$. Such a type describes the relation of $a$ to $A$ in the sense of the logic under consideration. In saturated models of a first order theory the type of $a$ over $A$ determines the orbit of $a$ under automorphisms of the monster model fixing $A$. The Galois type of $a$ over $A$ is only defined when $A$ is a model $M$. But then, it corresponds precisely to the orbit of $a$ under automorphisms of the monster model fixing $M$. Syntactic types have certain natural locality properties:

- locality: Any increasing chain of types has at most one upper bound;
- tameness: two distinct types differ on a finite set;
- compactness: an increasing chain of types has a realization.

The translations of these conditions to Galois types do not hold in general. We will show that when $N$ is an abelian group, Galois types of elements correspond to syntactic types of countable sequence. This means that these locality properties do hold. Since the translation rather than the specific property is the crucial issue here, we give the technical definition of only one of the properties.

**Definition 2.13.** (1) We say $K$ is $(\chi, \mu)$-tame if for any $N \in K$ with $|N| = \mu$ if $p, q, \in ga - S(N)$ and for every $N_0 \leq N$ with $|N_0| \leq \chi$, $p \restriction N_0 = q \restriction N_0$ then $q = p$.

2. $K$ is $(\chi, \infty)$-tame if it is $K$ is $(\chi, \mu)$-tame for all $\mu$.

3. The case of abelian groups

The main goal of this section is the proof of Theorem 0.3. First we note that closures in the sense of Definition 2.5 take a simpler form for abelian groups:

By Lemma 2.9, $\cl_B(X)$ is just the closure of $X$ with respect to divisibility by $p$ for each $p \in P$, that is, $\cl_B(X)$ is the set of all $y \in B$ such that for some $m$ which is a product of powers of primes in $P$, $my \in X$. Note that for any $A \preccurlyeq_K(P)$ $B \in K(P)$ and $b \in B$, $\cl_B(A, b)$ is countably generated over $A$.

This has corollaries concerning tameness and stability.

**Corollary 3.1.** If $N$ is an abelian group, the Galois type of $a$ over $M \in \perp N$ is determined by the quantifier-free type of a countable sequence associated with $a$. This implies $(\perp N, \preccurlyeq_N)$ is $(N_0, \infty)$-tame and stable in $\lambda$ if $\lambda^\omega = \lambda$.

**Proof.** Let $A \preccurlyeq_N B$ and $a \in B$. Then $\cl_B(Aa)$ is generated by some countable set $c$. So by Lemma 2.12, the Galois type of $a$ over $B$ is determined by the quantifier-free first order type of $c$ over $B$. This means that if $a$ and $a'$ have different Galois types over $B$, the associated sequences $\epsilon, \epsilon'$ have different quantifier-free types over $B$ and thus over a countable submodel $B_0$ of $B$; this is tameness. And the number of Galois types over a model of cardinality $\lambda$ is at most the number of quantifier-free types of $\omega$ sequences. Since over any module of cardinality $\lambda$ there are only $\lambda$ quantifier-free types of finite sequences, there are $\lambda^\omega$ types of $\omega$ sequences. □
The translation to quantifier-free types also gives full compactness and locality for Galois types in this context; see the chapter, Locality and Tameness, in [4] for precise definitions.

Now we can prove Theorem 0.3(1), that is, if $P$ is a nonempty set of primes of $\mathbb{Z}$ and $\lambda$ is an infinite cardinal, then $(K(P), \prec_{K(P)})$ is stable in $\lambda$ if and only if $\lambda^\omega = \lambda$. We just proved that $\lambda^\omega = \lambda$ is a sufficient condition for stability. Fix a prime $p$ in $P$. For a given infinite cardinal $\lambda$, fix an enumeration $\{f_i : i \in \lambda^\omega\}$ of $\lambda^\omega$ different one-one functions from $\omega$ to $\lambda$. Let $S' = \omega \times \lambda$, and let $A$ be the free abelian group with basis $S = \{e_s : s \in S'\}$. For each $i \in \lambda^\omega$, let $B_i$ be $F_i/K_i$ where $F_i$ is the free group on $S \cup \{b_i\} \cup \{z_{n,i} : n \in \omega\}$ and $K_i$ is the subgroup generated by

$$w_{n,i} = p^{n+1}z_{n,i} - b_i - \sum_{\ell=0}^n p^\ell e_{\ell,f_i(\ell)}.$$  

It is easy to check that this generating set is a basis. We show that the map taking $a \in A$ to $a + K_i$ embeds $A$ as a subgroup of $B_i$; indeed, suppose that $a = \sum_{s \in S'} c_s e_s$ and $a + K_i = 0$, that is,

$$\sum_{s \in S'} c_s e_s = \sum_{n \in \omega} d_n w_{n,i}.$$  

or

$$\sum_{s \in S'} c_s e_s = \sum_{n \in \omega} d_n \left(p^{n+1}z_{n,i} - b_i - \sum_{\ell=0}^n p^\ell e_{\ell,f_i(\ell)}\right)$$

where $c_s, d_n \in \mathbb{Z}$. This is an equation in $F_i$, and since $S \cup \{b_i\} \cup \{z_{n,i} : n \in \omega\}$ is a basis of $F_i$, we can equate coefficients of basis elements on each side. In particular, the coefficient of $z_{n,i}$ on the right is $d_n p^{n+1}$ and on the left is 0; thus $d_n = 0$. But then the right-hand side is zero, i.e. $a = 0$.

We also prove that $A$ embeds as a pure subgroup of $B_i$, which implies that it embeds as a $K(P)$-submodel, since $B_i$ is torsion-free. Aiming at a contradiction, suppose that $q$ is a prime and for some $a \in A$, $a + K_i$ is divisible by $q$ in $B_i$ but not in $A$. Say $a = \sum_{s \in S'} c_s e_s$ and

$$\sum_{s \in S'} c_s e_s = qy + \sum_{n \in \omega} d_n \left(p^{n+1}z_{n,i} - b_i - \sum_{\ell=0}^n p^\ell e_{\ell,f_i(\ell)}\right)$$

where $y \in F_i$ and some $c_s$ is not divisible by $q$. Comparing the coefficient of $b_i$ on both sides, we conclude that $\sum_{n \in \omega} d_n \equiv 0 \pmod{q}$; but then the coefficient of $e_s$ on the right is also congruent to 0 mod $q$, a contradiction.

Also, in $B_i/(A, b_i)$ the coset of $z_{n,i}$ has order $p^{n+1}$, so $z_{n,i}$ belongs to $cl_{B_i}(A, b_i)$ for all $n \in \omega$.

We claim that for all $i \neq j$, there is no isomorphism $\phi : cl_{B_i}(A, b_i) \rightarrow cl_{B_j}(A, b_j)$ which is the identity on $A$ and takes $b_i$ to $b_j$. This will suffice to prove Theorem 0.3(1) in view of Lemma 2.12(1). Suppose, to the contrary that $\phi$ is such an isomorphism. Let $n$ be minimal such that $f_i(n) \neq f_j(n)$. By construction, in $cl_{B_i}(A, b_i) \subseteq B_i$ we have

$$p^{n+1}z_{n,i} = b_i + \sum_{\ell=0}^n p^\ell e_{\ell,f_i(\ell)}$$

so applying $\phi$ we get

$$p^{n+1}\phi(z_{n,i}) = b_j + \sum_{\ell=0}^n p^\ell e_{\ell,f_i(\ell)}$$

in $B_j$. But by construction, in $B_j$ we have

$$p^{n+1}z_{n,j} = b_j + \sum_{\ell=0}^n p^\ell e_{\ell,f_j(\ell)}.$$  

Subtracting the last two equations, and taking into account the minimality of $n$, we get that $p^{n+1}$ divides $p^n(e_{n,f_i(n)} - e_{n,f_j(n)})$ in $B_j$. But this contradicts the purity of $A + K_j$ in $B_j$, so the proof of 0.3(1) is complete.
Now we take up the proof of 0.3(2). Suppose that $R$ is a p.i.d. and $P$ is a nonempty set of primes of cardinality $\kappa$ (finite or infinite). Let $\kappa' = \kappa + \omega = \max(\kappa, \omega)$. Fix an infinite cardinal $\lambda$. The argument in 3.1 generalizes to show that in $\mathbf{K}(P)$, the Galois type of an element is determined by the quantifier-free type of a sequence of length $\kappa'$, and hence, as in 0.3(1), $\lambda^{\kappa'} = \lambda$ is a sufficient condition for stability at $\lambda$. If two Galois types are different, the associated quantifier-free types must disagree (actually on finite set) and therefore the Galois types have different restrictions to an $M \in \mathbf{K}(P)$ with $|M| = LS(\mathbf{K}(P))$, so $(\mathbf{K}(P), \prec_{\mathbf{K}(P)})$ is $(LS(\mathbf{K}(P)), \infty)$-tame. If $\kappa' = \omega$ (i.e., $\kappa$ is at most countable), the argument in part (1) shows that $\lambda^{\omega} = \lambda$ is also necessary for stability. So we consider the case when $\kappa = \kappa'$ is an infinite (even uncountable) cardinal. Fix an enumeration $\{p_{\nu} : \nu < \kappa\}$ of the elements of $P$, and fix an enumeration $\{f_{i} : i \in \lambda^{\kappa}\}$ of $\lambda^{\kappa}$ different one-one functions from $\kappa$ to $\lambda$. Let $A$ be the free abelian group with basis $S = \{e_{\alpha} : \alpha \in \lambda\}$. For each $i \in \lambda^{\kappa}$, let $B_{i}$ be $F_{i}/K_{i}$, where $F_{i}$ is the free group on $S \cup \{b_{i}\} \cup \{z_{\nu,i}\}$ and $K_{i}$ is the subgroup generated by

$$\{p_{\nu}z_{\nu,i} - b_{i} - e_{f_{i}(\nu)} : \nu \in \kappa\}. \quad (1)$$

Once again, it is easy to check that this generating set is a basis and that the map taking $a \in A$ to $a + K_{i}$ embeds $A$ as a pure subgroup of $B_{i}$. Also, in $B_{i}/(A, b_{i})$ the coset of $z_{\nu,i}$ has order $p_{\nu}$, so $z_{\nu,i}$ belongs to $cl_{B_{i}}(A, b_{i})$ for all $\nu \in \kappa$.

Aiming at a contradiction, suppose that for some $i \neq j$, there is an isomorphism $\varphi : cl_{B_{i}}(A, b_{i}) \rightarrow cl_{B_{j}}(A, b_{j})$ which is the identity on $A$ and takes $b_{i}$ to $b_{j}$. Fix $\nu \in \kappa$ such that $f_{i}(\nu) \neq f_{j}(\nu)$. By construction, in $cl_{B_{i}}(A, b_{i}) \subseteq B_{i}$ we have

$$p_{\nu}z_{\nu,i} = b_{i} + e_{f_{i}(\nu)}$$

so applying $\varphi$ we get

$$p_{\nu}\varphi(z_{\nu,i}) = b_{j} + e_{f_{j}(\nu)}$$

in $B_{j}$. But by construction, in $B_{j}$ we have

$$p_{\nu}z_{\nu,j} = b_{j} + e_{f_{j}(\nu)}.$$

Subtracting the last two equations, we get that $p_{\nu}$ divides $e_{f_{i}(\nu)} - e_{f_{j}(\nu)}$ in $B_{j}$. But this contradicts the fact that $A$ is a pure subgroup of $B_{j}$ and completes the proof of 0.3(2).

We finish with a more specific comment about abelian groups; recall that if $P \neq \emptyset$, then $(\mathbf{K}(P), \prec_{\mathbf{K}(P)})$ is stable only in $\lambda$ with $\lambda^{\omega} = \lambda$. In contrast [5] shows that the class of all abelian groups under subgroups is stable in all infinite cardinalities. And this is exactly the case $(\mathbf{K}(P), \prec_{\mathbf{K}(P)})$ when $P$ is empty. So in this one case, $(\mathbf{K}(P), \prec_{\mathbf{K}(P)})$ is stable in all cardinalities.

One is naturally led to ask whether analogues to properties of the first order stability classification hold in this situation. Recall that a countable first-order theory that is not superstable has $2^{\kappa}$ models in every uncountable power. The analogous question for AECs is open; indeed, the choice of the appropriate version of superstable in this context is open. But it is easy to see for an abelian group $N$ that each $\frac{1}{\kappa}N$ has $2^{\kappa}$ models in each cardinal as each class contains a nonsuperstable group whose theory thus has $2^{\kappa}$ models of cardinality $\lambda$ and $\frac{1}{\kappa}N$ is closed under elementary equivalence since it is first-order axiomatizable.

**Remark 3.2.** The stability spectrum problem for arbitrary AECs has not been solved. There are explicit results for tame AECs in [15] and [7]. See also, for example, [20].

**Question 3.3.** (1) For which rings $R$ does each AEC of the form $(\frac{1}{\kappa}N, \prec_{N})$ admit intersections? (This holds for all Dedekind domains and all right artinian right hereditary rings, but not for all rings by Lemma 2.9, Remark 2.10(iii) and Example 2.11.)

(2) What is the stability spectrum of $(\frac{1}{\kappa}N, \prec_{N})$ for other rings $R$ and modules $N$? Does the condition that $(\frac{1}{\kappa}N, \prec_{N})$ is stable in all cardinals (or all cardinals beyond the continuum) provide any further algebraic conditions on $N$?
4. Further directions

These examples have provided illustrations for a number of notions of AEC; in particular, the notion of closure is clarified by providing classes where it does and does not hold. This family of examples also provides one explanation of how tameness can be obtained: the Galois type of an element is determined by the syntactic type of an associated short sequence. But tameness can hold for deeper reasons [8,6]; it would be interesting to explore when this simple explanation works. Here are some more specific questions:

**Question 4.1.** (1) For modules over rings other than \( \mathbb{Z} \), what are the tameness properties of \((\perp N, \prec N)\)?

(2) Does \((\perp N, \prec N)\) have finite character in the sense of Hyttinen–Kesälä [16]?

(3) For which \( R \) and \( N \) is \((\perp N, \prec N)\) axiomatizable (in infinitary logic)? One might expect to use \( L_{\kappa,\omega} \) if the ring had cardinality \( \kappa \).

(4) What can we say about the number of models in various cardinalities of \((\perp N, \prec N)\) (for general \( N \) and \( R \))?
