Conclusions: The current ex vivo swine model demonstrated decreased acute thrombogenicity in bioerodible polymer thin-strut Synergy as compared to bioerodible thick-strut Biomatrix Flex and fully bioresorbable Absorb, which confirms the acute protective function of bioerodible stent coatings and emphasizes the relevance of stent geometry in acute thrombogenicity.

Background: Transcatheter paravalvular leak closure (TPVLC) has become a viable and BVS (p< 0.05)(Figure). The number of platelet aggregation clots was the least in Synergy DES with a borderline significance difference compared to other stents.

Results: Enrollment started in 2010 and reported data is complete as of December 2013. From 64 referred patients 49, with either mechanical valves (n = 30) or stented bioprostheses, were found eligible for TPVLC. PVL location was mitral (n=29) or aortic. In the aortic group acute procedural success (APS) ratio was 100% and no MACCEs occurred. In the mitral group, TPVLC was successful on first attempt in 22 cases (4/4 in transapical and 18/25 in transeptal access). Following transeptal failure another transapical procedure was performed in 5 patients. TPVLC ultimately proved efficient in 89.7% of mitral PVLs with APS of 78%. When successful, it led to significant decrease of NT-proBNP – 167±21% vs. 45±14% at 45min, p<0.05 (Figure). The number of platelet aggregation clots was the least in Synergy DES with a borderline significance difference compared to other stents.

Conclusions: The current ex vivo swine model demonstrated decreased acute thrombogenicity in bioerodible polymer thin-strut Synergy as compared to bioerodible thick-strut Biomatrix Flex and fully bioresorbable Absorb, which confirms the acute protective function of bioerodible stent coatings and emphasizes the relevance of stent geometry in acute thrombogenicity.

Background: Transduction efficacy, delivery approaches and vector serotypes are representing major challenges for future cardiac gene therapy. The aim of this current study was to test not only the anterograde coronary approach for gene delivery but three different AAV serotypes (6, 7 and 9) in a pre-clinical large animal model.

Methods: The approach was tested in 19 chronically instrumented dogs which received the AAV vectors anterogradely intracoronarily. The left main coronary artery was cannulated with a Cobra1 catheter (5F) and a micro-infusion catheter (2.5F) was selectively advanced into LAD and RCX. The solution for infusion was prepared with normal saline, 1x1013 AAV particles, SubstanceP (0.25 µg/kg/min) and Adenosine (0.15mg/kg/min) and was injected slowly over 20min. Nitroglycerine was given i.v. (1µg/kg/min) to further enhance endothelial penetration of the virus. The coronary sinus was approached with a custom made balloon in eleven subjects. Hemodynamic data were recorded and infection efficacy was assessed using immunohistochemistry for eGFP after 30days.

Results: Procedure time was significantly longer in the cases with coronary sinus occlusion (60±10 vs. 90±24min, p<0.05). Mean arterial pressure and dp/dmax dropped in all cases due to the vasodilators (118±15 to 53±21mmHg and 2280±450 to 1421±414mmHg/sec). These effects were enhanced with coronary sinus blockage that infusion had to be discontinued several times due to hypotension. The eGFP-transduction rate with AAAV9 was heterogeneous within the myocardial layers (0.3-56%), with a higher transduction in the subendocardial layer (22-45%). There was no significant increase of eGFP-expression caused by the additional coronary sinus blockage (p=0.07). Comparing the different serotypes AAAV7 and AAAV9 have been more effective infecting LV tissue than AAAV6 (16±2%, 21±9% vs. 4±2%, p<0.05).

Conclusions: Anterograde cardiace gene delivery is feasible and comparatively effective. The addition of coronary sinus blockage did not increase efficiency significantly. Individual characteristics need to be taken into account selecting the optimal AAV serotype for translatable results.

A Novel 4.5-Fr CoKatte Catheter Facilitating Stent Delivery in Complex Lesion in the Coronary Artery
Akihiko Takahashi1, Norimasa Taniguchi1, Tetsuya Haté, Takeshi Yamada1, Yukio Mitaguchi1, Shunsuke Nakajima1

Background: The deployment of the stent sometimes associates with difficulty because of the unfavorable lesion characteristics including severe calcification or tortuous configuration of the vessel, and insufficient backup support of the guiding catheter. To address this issue, the small-sized straight inner catheter have been developed to access the lesion, where the stent to be implanted. Recently, a novel 4.5-Fr child catheter with hyper lubricity in outer surface to ease advancement of the catheter was developed to improve the success rate in stent delivery.

Methods: We retrospectively evaluated 51 consecutive patients, who underwent primary percutaneous coronary intervention with CoKatte catheter (Asahi Intecc Co., Ltd, Seta, Japan) after failure in delivering the stents with conventional procedure with 6-Fr guiding catheter between January 2011 and December 2013. CoKatte catheter is a straight catheter with 1.5mm in outer diameter, 120 cm in length, and compatible for 6-Fr guide catheter.

Results: The mean age of the patients was 75.3 years old and 29 male patients were included. Target vessels were comprised of 13 LADs, 7 LCXs, 27 RCA’s, and 4 SVGs. Trans-radial approach was performed in 41 patients. Six lesions were chronic total occlusion. Seven lesions required the lesion preparation with Rotablator (Boston Scientific Corp.) before stent delivery. For advancement and subsequent deep intubation of the catheter, anchor balloon technique was needed in 42 patients, otherwise the catheter could be advanced under support of the guide wire or the shaft of the balloon catheter. In all cases, stent delivery in the intended lesion was achieved. The complication related to deep insertion of the catheter including proximal dissection, air embolism, and severe ischemia were not observed.

Conclusions: This novel 4.5-Fr catheter is considered to contribute for facilitating stent delivery in the complex lesion in the coronary arteries.
