## Abstract

Tarski asked whether the arithmetic identities taught in high school are complete for showing all arithmetic equations valid for the natural numbers. The answer to this question for the language of arithmetic expressions using a constant for the number one and the operations of product and exponentiation is affirmative, and the complete equational theory also characterises isomorphism in the typed lambda calculus, where the constant for one and the operations of product and exponentiation respectively correspond to the unit type and the product and arrow type constructors. This paper studies isomorphisms in typed lambda calculi with empty and sum types from this viewpoint. Our main contribution is to show that a family of so-called Wilkie–Gurevič identities, that plays a pivotal role in the study of Tarski’s high school algebra problem, arises from type-theoretic isomorphisms. We thus close an open problem by establishing that the theory of type isomorphisms in the presence of product, arrow, and sum types (with or without the unit type) is not finitely axiomatisable. Further, we observe that for type theories with arrow, empty and sum types the correspondence between isomorphism and arithmetic equality generally breaks down, but that it still holds in some particular cases including that of type isomorphism with the empty type and equality with zero.

## Introduction

We study isomorphisms in typed lambda calculi with empty and sum types from the viewpoint of programming-language and type theory, category theory, and mathematical logic.

---

<sup>☆</sup> A preliminary version appeared in *Proceedings of the 17th Symposium on Logic in Computer Science (LICS)*, pp. 147–156. IEEE, Computer Society Press, 2002.

<sup>☆☆</sup> Part of this work was done during a visit of Marcelo Fiore to PPS - Université Paris 7 in July 2001 supported by the CNRS.

**Type isomorphism and programming languages.** Two data types are isomorphic if it is possible to convert data between them without loss of information. The equivalence relation on types induced by the notion of isomorphism allows one to abstract from inessential details in the representation of data in programming languages.

In Functional Programming, type isomorphisms provide a means to search functions by type (see [24,25,23,26,12,11,13]) and to match modules by specifications [1]. In proof assistants they are used to find proofs in libraries up to irrelevant syntactical details [10,4].

A characterisation of type isomorphisms has been obtained for monomorphic type systems with various combinations of the unit, product, and arrow type constructors [29,6,5], as well as for ML-style [11] and second-order polymorphism [14], and for linear lambda calculus [30] and multiplicative linear logic [2].

**Type isomorphism and category theory.** Type isomorphism in foundational theories of functional programming languages, like typed lambda calculi, can be studied by means of their associated categorical models. From this perspective, our investigations fall in the context of Lawvere and Schanuel’s *Objective Number Theory* [27,28], which is the study of addition, multiplication, and exponentiation of objects in suitable categories (see also [21, Section 2]). Indeed, we will be considering the equational theory of arithmetic expressions in the objective number theory of free bicartesian closed categories and relating it to that of the category of finite sets, where numerical equalities acquire a combinatorial meaning given by isomorphisms that provide so-called *combinatorial* or *bijection* proofs.

**Type isomorphism and Tarski’s high school algebra problem.** There is a connection between the characterisation of type isomorphisms in typed lambda calculi and some results in mathematical logic related to Tarski’s high school algebra problem [15]: for types built out of type constructors chosen amongst the unit, product, and arrow, two types are isomorphic if and only if their associated arithmetic expressions (obtained by interpreting the unit by the number one, product by multiplication, and arrow by exponentiation) are equal in the standard model of natural numbers. In these cases, type isomorphism (and numerical equality) is finitely axiomatisable and decidable; hence so is the equational theory of isomorphisms in cartesian closed categories. In the same vein, Soloviev [30] gave a complete axiomatisation of isomorphisms in symmetric monoidal closed categories, and Dosen and Petric [16] provided the arithmetic structure that exactly corresponds to these isomorphisms.

The question has been open as to whether such correspondence was limited to the case of the well-behaved unit, product, and arrow type constructors and, in particular, whether it could be extended to more problematic types involving the empty type and the sum type constructor. (From a practical perspective, one is interested in knowing whether type isomorphisms in the presence of sums are finitely axiomatisable, a definitive advantage when implementing decision procedures in library search tools like those described in [24,13].) To investigate these problems we devised a method for establishing normal forms in the typed lambda calculus with empty and sum types [17,3] and used it to study type isomorphism in this setting; this was crucial for establishing (a) below.

### Summary of results and organisation of the paper.

- (a) We show that a family of so-called Wilkie–Gurevič identities arise from type-theoretic isomorphisms and subsequently establish that the equational theory of type isomorphisms in the presence of the product, arrow, and sum type constructors is not finitely axiomatisable.
- (b) We observe that in the presence of arrow, empty and sum types, type isomorphism and arithmetic equality no longer coincide. However, the coincidence still holds for certain classes of arithmetic equations.

Section 1 recalls the basic definitions. Section 2 establishes the non-finite axiomatisability and separation results (a) and (b). Section 3 concludes with remarks and directions for further work.

## 1. The type theories

### 1.1. Product and sum types

**Syntax.** We present the type theory of product and sum types, including the empty ones. The set of types contains two distinguished type constants 1 and 0, a countable set of base types, and is closed under the product and sum type constructors. That is, types are defined by the grammar

$$\tau ::= \theta \mid 1 \mid \tau_1 \times \tau_2 \mid 0 \mid \tau_1 + \tau_2 \tag{1}$$

where  $\theta$  ranges over base types.

$$\begin{array}{c}
\frac{}{\Gamma, x : \tau, \Gamma' \vdash x : \tau} \qquad \frac{}{\Gamma \vdash \langle \rangle : \mathbb{1}} \\
\\
\frac{\Gamma \vdash t_i : \tau_i \quad (i = 1, 2)}{\Gamma \vdash \langle t_1, t_2 \rangle : \tau_1 \times \tau_2} \qquad \frac{\Gamma \vdash t : \tau_1 \times \tau_2}{\Gamma \vdash \pi_i(t) : \tau_i} \quad (i = 1, 2) \\
\\
\frac{\Gamma \vdash t : 0}{\Gamma \vdash \perp_\tau(t) : \tau} \\
\\
\frac{\Gamma \vdash t : \tau_i}{\Gamma \vdash \iota_i^{\tau_1, \tau_2}(t) : \tau_1 + \tau_2} \quad (i = 1, 2) \qquad \frac{\Gamma \vdash t : \tau_1 + \tau_2 \quad \Gamma, x_i : \tau_i \vdash t_i : \tau \quad (i = 1, 2)}{\Gamma \vdash \delta(t, x_1 : \tau_1, t_1, x_2 : \tau_2, t_2) : \tau} \\
\cdots \\
\frac{\Gamma, x : \tau_1 \vdash t : \tau}{\Gamma \vdash \lambda x : \tau_1. t : \tau_1 \rightarrow \tau} \qquad \frac{\Gamma \vdash t : \tau_1 \rightarrow \tau \quad \Gamma \vdash t_1 : \tau_1}{\Gamma \vdash t(t_1) : \tau}
\end{array}$$

Fig. 1. Typing rules.

Raw terms are defined by the grammar

$$t ::= x \mid \langle \rangle \mid \langle t_1, t_2 \rangle \mid \pi_1(t) \mid \pi_2(t) \mid \perp_\tau(t) \mid \iota_1^{\tau_1, \tau_2}(t) \mid \iota_2^{\tau_1, \tau_2}(t) \mid \delta(t, x_1 : \tau_1, t_1, x_2 : \tau_2, t_2) \quad (2)$$

where  $x$  ranges over (a countable set of) variables,  $\iota_1^{\tau_1, \tau_2}$  and  $\iota_2^{\tau_1, \tau_2}$  are the left and right injections into the sum type  $\tau_1 + \tau_2$ , and  $\delta$  is the usual binary case analysis (discriminating on the first argument and branching according to the second or third).

We write  $\Gamma \vdash t : \tau$  for the judgement “the term  $t$  has type  $\tau$  in context  $\Gamma$ ”. As usual, typing contexts are lists of distinct type variables together with type declarations. A term  $t$  is well typed in a context  $\Gamma$  if the judgement  $\Gamma \vdash t : \tau$  is derivable from the standard rules given in (the top part of) Fig. 1. The associated equational theory is given in Fig. 2. (Note that the congruence rule

$$\frac{\Gamma \vdash t = t' : 0}{\Gamma \vdash \perp_\tau(t) = \perp_\tau(t') : \tau}$$

is admissible.)

**Semantics.** A *bicartesian category* is a category with finite products ( $1, \times$ ) and finite coproducts ( $0, +$ ). Bicartesian categories for which the canonical map

$$(A \times B) + (A \times C) \longrightarrow A \times (B + C)$$

is an isomorphism for all objects  $A, B, C$  are called *distributive categories* [9,8]. We remark that in a distributive category the canonical map

$$0 \longrightarrow A \times 0$$

is an isomorphism for every object  $A$  (see, e.g., [9]).

We let  $\mathcal{D}[T]$  be the category with objects given by types over base types in  $T$  and morphisms  $\tau_1 \longrightarrow \tau_2$  given by equivalence classes  $[x : \tau_1 \vdash t : \tau_2]$  of well-typed terms under the equivalence identifying  $(x : \tau_1 \vdash t : \tau_2)$  and  $(x' : \tau_1 \vdash t' : \tau_2)$  iff the judgement  $x : \tau_1 \vdash t = t'[x'/x] : \tau_2$  is derivable. Composition is by substitution:

$$[x' : \tau_2 \vdash t' : \tau_3] \circ [x : \tau_1 \vdash t : \tau_2] = [x : \tau_1 \vdash t'[t/x] : \tau_3] \quad (3)$$

with identities given by

$$[x : \tau \vdash x : \tau]. \quad (4)$$

---

$$\begin{array}{c}
\frac{\Gamma \vdash t : \tau}{\Gamma \vdash t = t : \tau} \qquad \frac{\Gamma \vdash t = t' : \tau}{\Gamma \vdash t' = t : \tau} \qquad \frac{\Gamma \vdash t_1 = t_2 : \tau \quad \Gamma \vdash t_2 = t_3 : \tau}{\Gamma \vdash t_1 = t_3 : \tau} \\
\hline
\frac{\Gamma \vdash t : 1}{\Gamma \vdash t = \langle \rangle : 1} \\
\hline
\frac{\Gamma \vdash t_i = t'_i : \tau_i \quad (i = 1, 2)}{\Gamma \vdash \langle t_1, t_2 \rangle = \langle t'_1, t'_2 \rangle : \tau_1 \times \tau_2} \qquad \frac{\Gamma \vdash t = t' : \tau_1 \times \tau_2}{\Gamma \vdash \pi_i(t) = \pi_i(t') : \tau_i} \quad (i = 1, 2) \\
\frac{\Gamma \vdash t_1 : \tau_1 \quad \Gamma \vdash t_2 : \tau_2}{\Gamma \vdash \pi_i(\langle t_1, t_2 \rangle) = t_i : \tau_i} \quad (i = 1, 2) \qquad \frac{\Gamma \vdash t : \tau_1 \times \tau_2}{\Gamma \vdash t = \langle \pi_1(t), \pi_2(t) \rangle : \tau_1 \times \tau_2} \\
\hline
\frac{\Gamma \vdash t = t' : \tau_i}{\Gamma \vdash l_i^{\tau_1, \tau_2}(t) = l_i^{\tau_1, \tau_2}(t') : \tau_1 + \tau_2} \quad (i = 1, 2) \\
\frac{\Gamma \vdash t = t' : \tau_1 + \tau_2 \quad \Gamma, x_i : \tau_i \vdash t_i = t'_i : \tau \quad (i = 1, 2)}{\Gamma \vdash \delta(t, x_1, t_1, x_2, t_2) = \delta(t', x_1, t'_1, x_2, t'_2) : \tau} \\
\frac{\Gamma \vdash t : 0 \quad \Gamma \vdash t' : \tau}{\Gamma \vdash \perp_\tau(t) = t' : \tau} \\
\frac{\Gamma \vdash t : \tau_j \quad \Gamma, x_i : \tau_i \vdash t_i : \tau \quad (i = 1, 2)}{\Gamma \vdash \delta(l_j^{\tau_1, \tau_2}(t), x_1, t_1, x_2, t_2) = t_j[t/x_j] : \tau} \quad (j = 1, 2) \\
\frac{\Gamma \vdash t : \tau_1 + \tau_2 \quad \Gamma, x : \tau_1 + \tau_2 \vdash t' : \tau}{\Gamma \vdash \delta(t, x_1, t'[l_1^{\tau_1, \tau_2}(x_1)/x], x_2, t'[l_2^{\tau_1, \tau_2}(x_2)/x]) = t'[t/x] : \tau}
\end{array}$$

---

Fig. 2. Equational rules of the type theory for product and sum types.

The category  $\mathcal{D}[T]$  is canonically a distributive category, with terminal object 1 and initial object 0, and with products and sums respectively given by the projections

$$[x : \tau_1 \times \tau_2 \vdash \pi_i(x) : \tau_i] : \tau_1 \times \tau_2 \longrightarrow \tau_i \quad (i = 1, 2)$$

and the injections

$$[x : \tau_i \vdash l_i^{\tau_1, \tau_2}(x) : \tau_1 + \tau_2] : \tau_i \longrightarrow \tau_1 + \tau_2 \quad (i = 1, 2).$$

Further,  $\mathcal{D}[T]$  is the free distributive category on the set of base types  $T$  in the sense that for every distributive category  $\mathcal{S}$  with distinguished products and sums and interpretation  $\mathcal{I} : T \longrightarrow \mathcal{S}$ , there exists a unique functor  $\mathcal{I}[\_ ] : \mathcal{D}[T] \longrightarrow \mathcal{S}$  preserving the product and sum structures. Thus, the interpretation of the type theory in distributive categories is sound and complete.

Note, in particular, that the interpretation of types induced by  $\mathcal{I} : T \longrightarrow \mathcal{S}$  is given by

$$\begin{aligned}
\mathcal{I}[\theta] &= \mathcal{I}(\theta) \quad (\theta \in T), & \mathcal{I}[1] &= 1, & \mathcal{I}[\tau_1 \times \tau_2] &= \mathcal{I}[\tau_1] \times \mathcal{I}[\tau_2] \\
\mathcal{I}[0] &= 0, & \mathcal{I}[\tau_1 + \tau_2] &= \mathcal{I}[\tau_1] + \mathcal{I}[\tau_2].
\end{aligned} \tag{5}$$

$$\begin{array}{c}
\frac{\Gamma \vdash t : \tau}{\Gamma \vdash t = t : \tau} \qquad \frac{\Gamma \vdash t = t' : \tau}{\Gamma \vdash t' = t : \tau} \qquad \frac{\Gamma \vdash t_1 = t_2 : \tau \quad \Gamma \vdash t_2 = t_3 : \tau}{\Gamma \vdash t_1 = t_3 : \tau} \\
\cdots \\
\frac{\Gamma \vdash t : 1}{\Gamma \vdash t = \langle \rangle : 1} \\
\cdots \\
\frac{\Gamma \vdash t_1 : \tau_1 \quad \Gamma \vdash t_2 : \tau_2}{\Gamma \vdash \pi_i \langle t_1, t_2 \rangle = t_i : \tau_i} \quad (i = 1, 2) \qquad \frac{\Gamma \vdash t : \tau_1 \times \tau_2}{\Gamma \vdash t = \langle \pi_1(t), \pi_2(t) \rangle : \tau_1 \times \tau_2} \\
\cdots \\
\frac{\Gamma, x : \tau_1 \vdash t : \tau \quad \Gamma \vdash t_1 : \tau_1}{\Gamma \vdash (\lambda x : \tau_1. t)(t_1) = t[t_1/x] : \tau} \qquad \frac{\Gamma \vdash t : \tau_1 \rightarrow \tau}{\Gamma \vdash t = \lambda x : \tau_1. t(x) : \tau_1 \rightarrow \tau} \quad (x \notin \text{FV}(t)) \\
\cdots \\
\frac{\Gamma \vdash t : \tau_1 \rightarrow \tau \quad \Gamma \vdash t_1 = t'_1 : \tau_1}{\Gamma \vdash t(t_1) = t(t'_1) : \tau} \qquad \frac{\Gamma, x : \tau_1 \vdash t = t' : \tau}{\Gamma \vdash \lambda x : \tau_1. t = \lambda x : \tau_1. t' : \tau_1 \rightarrow \tau} \\
\cdots \\
\frac{\Gamma \vdash t : 0 \quad \Gamma \vdash t' : \tau}{\Gamma \vdash \perp_\tau(t) = t' : \tau} \\
\cdots \\
\frac{\Gamma \vdash t : \tau_j \quad \Gamma, x_i : \tau_i \vdash t_i : \tau \quad (i = 1, 2)}{\Gamma \vdash \delta(t_j^{\tau_1, \tau_2}(t), x_1 : \tau_1. t_1, x_2 : \tau_2. t_2) = t_j[t/x_j] : \tau} \quad (j = 1, 2) \\
\cdots \\
\frac{\Gamma \vdash t : \tau_1 + \tau_2 \quad \Gamma, x : \tau_1 + \tau_2 \vdash t' : \tau}{\Gamma \vdash \delta(t, x_1 : \tau_1. t'[t_1^{\tau_1, \tau_2}(x_1)/x], x_2 : \tau_2. t'[t_2^{\tau_1, \tau_2}(x_2)/x]) = t'[t/x] : \tau}
\end{array}$$

Fig. 3. Equational rules of the typed lambda calculus with sum types.

## 1.2. Product, arrow, and sum types

**Syntax.** The typed lambda calculus with sums (see, e.g., [20]) has types as in (1) extended as follows:

$$\tau ::= \cdots \mid \tau_1 \rightarrow \tau_2.$$

The raw terms are as in (2) extended by abstractions and applications:

$$t ::= \cdots \mid \lambda x : \tau. t \mid t_1(t_2).$$

A term  $t$  is well typed in a context  $\Gamma$  if the judgement  $\Gamma \vdash t : \tau$  is derivable from the rules given in Fig. 1. The associated equational theory is given in Fig. 3. (Note that the congruence rule

$$\frac{\Gamma, x : \tau \vdash t : \tau' \quad \Gamma \vdash t_1 = t_2 : \tau}{\Gamma \vdash t[t_1/x] = t[t_2/x] : \tau'}$$

is admissible.)

**Semantics.** A cartesian closed category (CCC) is a category with finite products and exponentials ( $\Rightarrow$ ). Bicartesian closed categories are referred to as BiCCCs; they are, of course, distributive (see, e.g., [20]).

We let  $\mathcal{F}_{0,+}[T]$  be the category with objects given by types over base types in  $T$  and morphisms  $\tau_1 \longrightarrow \tau_2$  given by equivalence classes  $[x : \tau_1 \vdash t : \tau_2]$  of well-typed terms under the equivalence identifying  $(x : \tau_1 \vdash t : \tau_2)$  and  $(x' : \tau_1 \vdash t' : \tau_2)$  iff the judgement  $x : \tau_1 \vdash t = t'[x/x'] : \tau_2$  is derivable. Composition and identities are as in (3)

and (4). Further, we define  $\mathcal{F}_+[T]$  analogously by omitting the empty type together with its associated constructor and equations throughout.

The category  $\mathcal{F}_{0,+}[T]$  is canonically a BiCCC, with terminal object 1 and initial object 0, and with products, exponentials, and sums respectively given by the projections

$$[x : \tau_1 \times \tau_2 \vdash \pi_i(x) : \tau_i] : \tau_1 \times \tau_2 \longrightarrow \tau_i \quad (i = 1, 2),$$

the evaluation map

$$[x : (\tau_1 \rightarrow \tau_2) \times \tau_1 \vdash (\pi_1(x))(\pi_2(x)) : \tau_2] : (\tau_1 \Rightarrow \tau_2) \times \tau_1 \longrightarrow \tau_2,$$

and the injections

$$[x : \tau_i \vdash \iota_i^{\tau_1, \tau_2}(x) : \tau_1 + \tau_2] : \tau_i \longrightarrow \tau_1 + \tau_2 \quad (i = 1, 2).$$

Further,  $\mathcal{F}_{0,+}[T]$  is the free BiCCC on the set of base types  $T$  in the sense that for every BiCCC  $\mathcal{S}$  with distinguished structure and interpretation  $\mathcal{I} : T \longrightarrow \mathcal{S}$ , there exists a unique functor  $\mathcal{I}[\_ ] : \mathcal{F}_{0,+}[T] \longrightarrow \mathcal{S}$  preserving the BiCC structure. Thus, the interpretation of the type theory in BiCCCs is sound and complete (see, e.g., [20]). Of course, an analogous result holds for  $\mathcal{F}_+[T]$  with respect to CC structure with binary sums.

Note that the interpretation of types induced by  $\mathcal{I} : T \longrightarrow \mathcal{S}$  is as in (5) together with

$$\mathcal{I}[\tau_1 \rightarrow \tau_2] = \mathcal{I}[\tau_1] \Rightarrow \mathcal{I}[\tau_2].$$

## 2. Tarski's high school algebra problem and type isomorphisms

**Tarski's high school algebra problem.** Tarski [15] asked whether the equational theory  $\mathcal{E}$  of the usual arithmetic identities

$$(\mathcal{E}_1) \quad 1 \cdot x = x \quad (\mathcal{E}_2) \quad x \cdot y = y \cdot x \quad (\mathcal{E}_3) \quad (x \cdot y) \cdot z = x \cdot (y \cdot z)$$

$$(\mathcal{E}_4) \quad x^1 = x \quad (\mathcal{E}_5) \quad 1^x = 1$$

$$(\mathcal{E}_6) \quad x^{y \cdot z} = (x^y)^z \quad (\mathcal{E}_7) \quad (x \cdot y)^z = x^z \cdot y^z$$

$$(\mathcal{E}_8) \quad x + y = y + x \quad (\mathcal{E}_9) \quad (x + y) + z = x + (y + z)$$

$$(\mathcal{E}_{10}) \quad x \cdot (y + z) = x \cdot y + x \cdot z \quad (\mathcal{E}_{11}) \quad x^{(y+z)} = x^y \cdot x^z$$

that are taught in high school is complete for the standard model of positive natural numbers. He conjectured that it was, but was not able to prove the result. Martin [22] showed that the equation  $(x^y)^z = (x^z)^y$  is complete for the standard model  $\langle N, \uparrow \rangle$  of positive natural numbers with exponentiation, and that the identities  $(\mathcal{E}_2)$ ,  $(\mathcal{E}_3)$ ,  $(\mathcal{E}_6)$ , and  $(\mathcal{E}_7)$  are complete for the standard model  $\langle N, \cdot, \uparrow \rangle$  of positive natural numbers with multiplication and exponentiation. Further, he exhibited the identity

$$(x^u + x^u)^v \cdot (y^v + y^v)^u = (x^v + x^v)^u \cdot (y^u + y^u)^v$$

that is not provable in the restriction of  $\mathcal{E}$  to the language without the constant 1.

Wilkie [31] established Tarski's conjecture in the negative. Indeed, by a proof-theoretic analysis, he showed that the identity

$$(A^x + B^x)^y \cdot (C^y + D^y)^x = (A^y + B^y)^x \cdot (C^x + D^x)^y$$

where

$$A = 1 + x, \quad B = 1 + x + x^2, \quad C = 1 + x^3, \quad D = 1 + x^2 + x^4$$

is not provable in  $\mathcal{E}$ .

Gurevič later gave an argument using an ad hoc countermodel [18] and, more importantly, showed that there is no finite axiomatisation for the valid equations in the standard model  $\langle N, 1, \cdot, \uparrow, + \rangle$  of positive natural numbers with one, multiplication, exponentiation, and addition [19]. He did this by producing an infinite family of equations such that for every sound finite set of axioms one of the equations can be shown not to follow. Gurevič's identities are the following:

$$(A^x + B_n^x)^{2^x} \cdot (C_n^{2^x} + D_n^{2^x})^x = (A^{2^x} + B_n^{2^x})^x \cdot (C_n^x + D_n^x)^{2^x} \quad (n \geq 3 \text{ odd}) \quad (6)$$

where

$$A = 1 + x,$$

$$B_n = 1 + x + \cdots + x^{n-1} = \sum_{i=0}^{n-1} x^i,$$

$$C_n = 1 + x^n,$$

$$D_n = 1 + x^2 + \cdots + x^{2(n-1)} = \sum_{i=0}^{n-1} x^{2i}.$$

**Type isomorphisms.** The equations in  $\mathcal{E}$  together with the following ones:

$$(\mathcal{D}_1) \quad x \cdot 0 = 0 \quad (\mathcal{D}_2) \quad x + 0 = x$$

have a clear combinatorial interpretation which is made evident when interpreting them as isomorphisms in the category of finite sets and functions  $\mathbf{F}$ , or indeed in any BiCCC, under the obvious translation given below:

$$\begin{aligned} \bar{x} = x \text{ (} x \text{ a variable),} \quad \bar{1} = 1, \quad \overline{e_1 \cdot e_2} = \overline{e_1} \times \overline{e_2}, \quad \overline{e_2^{e_1}} = \overline{e_1} \rightarrow \overline{e_2}, \\ \bar{0} = 0, \quad \overline{e_1 + e_2} = \overline{e_1} + \overline{e_2}. \end{aligned}$$

The isomorphisms realising the translations of the equations in  $\mathcal{E}$  are well known. For instance, those associated with the equation  $(\mathcal{E}_{11})$  are given by

$$f : \tau_1 + \tau_2 \rightarrow \tau \vdash \langle \lambda x_1 : \tau_1. f(t_1^{\tau_1, \tau_2}(x_1)), \lambda x_2 : \tau_2. f(t_2^{\tau_1, \tau_2}(x_2)) \rangle : (\tau_1 \rightarrow \tau) \times (\tau_2 \rightarrow \tau)$$

and

$$p : (\tau_1 \rightarrow \tau) \times (\tau_2 \rightarrow \tau) \vdash \lambda x : \tau_1 + \tau_2. \delta(x, x_1 : \tau_1. (\pi_1(p))(x_1), x_2 : \tau_2. (\pi_2(p))(x_2)) : \tau_1 + \tau_2 \rightarrow \tau.$$

(Note that the equation

$$x \cdot 0^x = 0$$

corresponding to the type isomorphism

$$\theta \times (\theta \rightarrow 0) \cong 0$$

has no obvious combinatorial meaning; though it corresponds logically to the intuitionistic tautology  $(p \wedge \neg p) \leftrightarrow \perp$ .)

Thus, for arithmetic expressions  $e_1$  and  $e_2$  in the language with the constant 1, the operations  $\cdot$ ,  $\uparrow$ ,  $+$ , and unknowns in a set  $U$ , we have the chain of implications

$$\begin{aligned} \mathcal{E} \vdash e_1 = e_2 &\implies \overline{e_1} \cong \overline{e_2} \text{ in } \mathcal{F}_+[U] \\ &\implies \mathbf{F} \models \overline{e_1} = \overline{e_2} \\ &\implies N \models e_1 = e_2 \end{aligned} \quad (7)$$

where, for types  $\tau_1$  and  $\tau_2$  and a category  $\mathcal{S}$ , we write  $\mathcal{S} \models \tau_1 = \tau_2$  whenever the identity  $\tau_1 = \tau_2$  holds as an isomorphism in  $\mathcal{S}$ ; that is, for all interpretations  $\mathcal{I}$  of base types in  $\mathcal{S}$ , it holds that  $\mathcal{I}[\tau_1] \cong \mathcal{I}[\tau_2]$  in  $\mathcal{S}$ . (Note that the statements  $\tau_1 \cong \tau_2$  in  $\mathcal{F}_{0,+}[U]$  and  $\mathcal{F}_{0,+}[U] \models \tau_1 = \tau_2$  are equivalent, and that they amount to type isomorphism in the equational theory of the typed lambda calculus with empty and sum types.) The last implication in (7) is easily established by observing that two finite sets are isomorphic iff they have the same cardinality, and that the type constructors on finite sets coincide with cardinal arithmetic.

The implications as in (7) for the cartesian closed case have been shown to be equivalences [29,5]. The rest of the paper is devoted to studying the extent to which these implications can be reversed in type theories with empty and sum types.

### 2.1. Product and sum types

We consider the case of distributive categories: the categorical counterpart of the type theory with unit and empty types, and product and sum type constructors.

For  $\mathcal{D}$  the equational theory consisting of the identities  $(\mathcal{E}_1)$ ,  $(\mathcal{E}_2)$ ,  $(\mathcal{E}_3)$ ,  $(\mathcal{E}_8)$ ,  $(\mathcal{E}_9)$ ,  $(\mathcal{E}_{10})$  and  $(\mathcal{D}_1)$ ,  $(\mathcal{D}_2)$ , we have the following result.

**Proposition 2.1.** *For arithmetic expressions  $e_1$  and  $e_2$  in the language given by  $1, 0, \cdot, +$  and with unknowns in a set  $U$ , the following statements are equivalent.*

- (1)  $\mathcal{D} \vdash e_1 = e_2$ .
- (2)  $\overline{e_1} \cong \overline{e_2}$  in  $\mathcal{D}[U]$ .
- (3)  $\mathbf{F} \models \overline{e_1} = \overline{e_2}$ .
- (4)  $N_0 \models e_1 = e_2$ .

The chain of implications (1)  $\Rightarrow$  (2)  $\Rightarrow$  (3)  $\Rightarrow$  (4) are straightforward, whilst the implication (4)  $\Rightarrow$  (1) amounts to the completeness of  $\mathcal{D}$  for the standard model of natural numbers. This result is folklore (see, for instance, [7]) and we include it below.

**Lemma 2.2.** *The equational theory  $\mathcal{D}$  is complete for the standard model  $\langle N_0, 1, 0, \cdot, + \rangle$  of natural numbers.*

**Proof.** Any expression in the language of variables,  $1, 0, \cdot, +$  can be rewritten, using the equations in  $\mathcal{D}$ , into a canonical polynomial form, which can in fact be made unique.

Now,  $N_0 \models e_1 = e_2$  iff, for the corresponding canonical polynomial forms  $p_1$  and  $p_2$  of  $e_1$  and  $e_2$  respectively,  $N_0 \models p_1 = p_2$ , and this is equivalent to  $p_1$  and  $p_2$  being the same polynomial (i.e., syntactically equal) as the polynomial  $p_1 - p_2$  with coefficients in the field of rational numbers has an infinite number of zeros and hence is null.

Thus, the lemma follows: if  $e_1 = e_2$  holds in the standard model then, using  $\mathcal{D}$ , the expression  $e_1$  can be transformed into its canonical polynomial form which can in turn be transformed into the expression  $e_2$ .  $\square$

Notice that the argument in the above proof shows that  $\mathcal{D}$  is decidable. As a further corollary, we have the following *multiplicative cancellation* property.

**Corollary 2.3.** *For every non-empty type  $\tau$  (viz.,  $\tau \not\cong 0$ ) in  $\mathcal{D}[T]$ , we have that*

$$\tau_1 \times \tau \cong \tau_2 \times \tau \text{ in } \mathcal{D}[T] \implies \tau_1 \cong \tau_2 \text{ in } \mathcal{D}[T]$$

for every pair of types  $\tau_1$  and  $\tau_2$  in  $\mathcal{D}[T]$ .

It is interesting to note that in the further presence of exponentials, the above multiplicative cancellation property does not always hold. Indeed, for all types  $\tau$  in  $\mathcal{F}_{0,+}[T]$ , we have the isomorphism

$$(\tau \rightarrow 0) \times \tau \cong 0 \times \tau \text{ in } \mathcal{F}_{0,+}[T],$$

from which the cancellation of  $\tau$  does not generally yield an isomorphism (for instance,  $\theta \rightarrow 0 \not\cong 0$  for all  $\theta \in T$ ).

## 2.2. Product, arrow, and sum types

Aiming at understanding type isomorphism in the presence of product, arrow, and sum types, it is natural to ask whether Gurevič's equations are also type isomorphisms.

We first consider two ways of establishing the identities (6) for the natural numbers respectively due to Wilkie and Gurevič.

*Wilkie's method.* Use that  $C_n = A \cdot E_n$  and  $D_n = B_n \cdot E_n$  for  $E_n = 1 - x + \dots + x^{n-1} = \sum_{i=0}^{n-1} (-1)^i x^i$ .

*Gurevič's method.* Multiply the left hand side of (6) by  $(D_n^x)^{2^x}$  and using the equation  $A \cdot D_n = B_n \cdot C_n$  twice establish the right hand side of (6) multiplied by  $(D_n^{2^x})^x$ ; conclude (6) by multiplicative cancellation of  $(D_n^x)^{2^x} = (D_n^{2^x})^x$ .

Since the above methods respectively use negative numbers (which do not have a type-theoretic counterpart) and multiplicative cancellation (which is not known to be type theoretically sound), we speculated that Gurevič's identities did not hold as isomorphisms. Hence, we set out to prove that no term between the types corresponding to Gurevič's equations is an isomorphism by a careful study and analysis of normal forms in the typed lambda calculus with empty and sum types [17,3].

**Generalised Wilkie–Gurevič identities.** To simplify the study of the normal forms between the types induced by the expressions in (6), we introduced the following generalised Wilkie–Gurevič identities with no constants:

$$(A^u + B_n^u)^v \cdot (C_n^v + D_n^v)^u = (A^v + B_n^v)^u \cdot (C_n^u + D_n^u)^v \quad (n \geq 3 \text{ odd}) \quad (8)$$

where

$$\begin{aligned} A &= y + x \\ B_n &= y^{n-1} + y^{n-2}x + \dots + x^{n-1} = \sum_{i=0}^{n-1} y^{n-(i+1)}x^i \\ C_n &= y^n + x^n \\ D_n &= y^{2(n-1)} + y^{2(n-2)}x^2 + \dots + x^{2(n-1)} = \sum_{i=0}^{n-1} y^{2(n-(i+1))}x^{2i}. \end{aligned} \quad (9)$$

Notice that on replacing  $y$  by  $1$ ,  $u$  by  $x$ , and  $v$  by  $2^x$  in (8) one obtains the Eq. (6). Hence the non-finite axiomatisability result does not depend on the presence of constants in the language.

**Corollary 2.4.** *The equational theory of  $\langle N, \cdot, \uparrow, + \rangle$  is not finitely axiomatisable.*

**The generalised Wilkie–Gurevič identities are isomorphisms of types.** Analysing the normal forms between the types corresponding to the generalised Wilkie–Gurevič identities (8) for the case  $n = 3$ , we found an isomorphism. The lemma below gives a general construction, which provides a type theoretic method for establishing the identities and that further exhibits their combinatorial content. (Note that this construction is more general than what is needed to establish that the Generalised Wilkie–Gurevič family of identities are isomorphisms.)

**Lemma 2.5.** *For types  $A, B, C, D, U, V, X, Y$  and mutually inverse closed terms  $\varphi : A \times D \rightarrow C \times B$ ,  $\phi : C \times B \rightarrow A \times D$ , and  $\varepsilon : U \times V \rightarrow X \times Y$ ,  $\epsilon : X \times Y \rightarrow U \times V$  in the typed lambda calculus with empty and sum types, the terms (where we write  $\tau^\sigma$  for  $\sigma \rightarrow \tau$ )*

$$\begin{aligned} &t_{A,B,C,D,U,V,X,Y}[\varphi, \phi, \varepsilon, \epsilon] : \\ &(A^U + B^U)^V \times (C^X + D^X)^Y \rightarrow (A^X + B^X)^Y \times (C^U + D^U)^V \end{aligned}$$

and

$$t_{A,B,C,D,X,Y,U,V}[\varphi, \phi, \epsilon, \varepsilon] : (A^X + B^X)^Y \times (C^U + D^U)^V \rightarrow (A^U + B^U)^V \times (C^X + D^X)^Y$$

given by

$$\begin{aligned} &t_{A,B,C,D,U,V,X,Y}[\varphi, \phi, \varepsilon, \epsilon] \\ &\stackrel{\text{def}}{=} \lambda h : (A^U + B^U)^V \times (C^X + D^X)^Y. \langle p_{A,B,C,D,U,V,X,Y}[\varphi, \phi, \epsilon, \pi_1 h, \pi_2 h], \\ &\quad p_{C,D,A,B,X,Y,U,V}[\phi, \varphi, \varepsilon, \pi_2 h, \pi_1 h] \rangle \end{aligned}$$

where

$$\begin{aligned} &p_{A,B,C,D,U,V,X,Y}[\varphi, \phi, \gamma, f, g] \\ &\stackrel{\text{def}}{=} \lambda y : Y. \delta( g(y), \\ &\quad g_1 : C^X. \iota_1^{A^X, B^X} ( \lambda x : X. \delta( f(\pi_2(\gamma(x, y))), \\ &\quad\quad f_1 : A^U. f_1(\pi_1(\gamma(x, y))), \\ &\quad\quad f_2 : B^U. \pi_1(\phi(g_1(x), f_2(\pi_1(\gamma(x, y)))))) ) ), \\ &\quad g_2 : D^X. \iota_2^{A^X, B^X} ( \lambda x : X. \delta( f(\pi_2(\gamma(x, y))), \\ &\quad\quad f_1 : A^U. \pi_2(\varphi(f_1(\pi_1(\gamma(x, y))), g_2(x))), \\ &\quad\quad f_2 : B^U. f_2(\pi_1(\gamma(x, y))) ) ) ) \end{aligned}$$

are mutually inverse.

**Proof.** See Appendix A.  $\square$

For the expressions (9) the identity  $A \cdot D_n = C_n \cdot B_n$  can be proved from the standard axioms. Thus, there are mutually inverse closed terms  $\varphi_n : \mathcal{A} \times \mathcal{D}_n \rightarrow \mathcal{C}_n \times \mathcal{B}_n$  and  $\phi_n : \mathcal{C}_n \times \mathcal{B}_n \rightarrow \mathcal{A} \times \mathcal{D}_n$ , where we write  $\mathcal{A}$  for  $\overline{A}$ ,  $\mathcal{B}_n$  for  $\overline{B_n}$ ,  $\mathcal{C}_n$  for  $\overline{C_n}$ , and  $\mathcal{D}_n$  for  $\overline{D_n}$ . It follows that

$$t_{\mathcal{A}, \mathcal{B}_n, \mathcal{C}_n, \mathcal{D}_n, \mathcal{U}, \mathcal{V}, \mathcal{V}, \mathcal{U}}[\varphi_n, \phi_n, \lambda x : \mathcal{U} \times \mathcal{V}. \langle \pi_2 x, \pi_1 x \rangle, \lambda x : \mathcal{V} \times \mathcal{U}. \langle \pi_2 x, \pi_1 x \rangle]$$

is an isomorphism with inverse

$$t_{\mathcal{A}, \mathcal{B}_n, \mathcal{C}_n, \mathcal{D}_n, \mathcal{V}, \mathcal{U}, \mathcal{U}, \mathcal{V}}[\varphi_n, \phi_n, \lambda x : \mathcal{V} \times \mathcal{U}. \langle \pi_2 x, \pi_1 x \rangle, \lambda x : \mathcal{U} \times \mathcal{V}. \langle \pi_2 x, \pi_1 x \rangle].$$

Hence we have the following result.

**Corollary 2.6.** *The equational theory of type isomorphism in cartesian closed categories with binary coproducts is not finitely axiomatisable.*

### 2.3. Empty and sum types

In the presence of arrow and *both* empty and sum types we observe that not all equations that hold as isos in the category of finite sets hold in the type theory. Indeed, writing  $\neg\tau$  for  $\tau \rightarrow 0$ , we have that

$$\mathbf{F} \models \neg\neg\theta \rightarrow \theta = \theta + \neg\theta$$

but as the formula  $(\neg\neg p \rightarrow p) \rightarrow (\neg p \vee p)$  is a classical tautology which is not intuitionistically valid there is no term of type  $(\neg\neg\theta \rightarrow \theta) \rightarrow (\neg\theta + \theta)$ . Another such equation, derived from the above by taking the base type to be negated and using that  $1 \cong \neg\neg\neg\theta \rightarrow \neg\theta$ , is

$$\mathbf{F} \models 1 = \neg\theta + \neg\neg\theta. \tag{10}$$

Thus, in general,  $\mathbf{F} \models \tau_1 = \tau_2$  does not imply  $\tau_1 \cong \tau_2$  in  $\mathcal{F}_{0,+}[T]$ . However, we have the following result.

**Proposition 2.7.** *For every pair of types  $\tau_1$  and  $\tau_2$  in the typed lambda calculus with empty and sum types over a set of base types  $T$ , the following statements are equivalent.*

- (1)  $\neg\tau_1 \cong \neg\tau_2$  in  $\mathcal{F}_{0,+}[T]$ .
- (2) The formula  $\neg\overline{\tau_1} \leftrightarrow \neg\overline{\tau_2}$  is an intuitionistic tautology, where

$$\begin{aligned} \overline{\theta} = \theta \ (\theta \in T), \quad \overline{1} = \top, \quad \overline{\tau_1 \times \tau_2} = \overline{\tau_1} \wedge \overline{\tau_2}, \quad \overline{\tau_1 \rightarrow \tau_2} = \overline{\tau_1} \rightarrow \overline{\tau_2}, \\ \overline{0} = \perp, \quad \overline{\tau_1 + \tau_2} = \overline{\tau_1} \vee \overline{\tau_2}. \end{aligned}$$

- (3) For every interpretation  $\mathcal{I}$  of base types in the category of finite sets  $\mathbf{F}$ ,  $\mathcal{I}[\tau_1] = 0$  iff  $\mathcal{I}[\tau_2] = 0$ .
- (4)  $\mathbf{F} \models \neg\tau_1 = \neg\tau_2$ .
- (5)  $N_0 \models 0^{e_1} = 0^{e_2}$ , where  $\overline{e_1} = \tau_1$  and  $\overline{e_2} = \tau_2$ .

**Proof.** The equivalences (1)  $\Leftrightarrow$  (2) and (3)  $\Leftrightarrow$  (4)  $\Leftrightarrow$  (5), and the implication (1)  $\Rightarrow$  (4) are straightforward.

To establish the implication (3)  $\Rightarrow$  (2) we will use the (Gödel–Gentzen) negative translation  $\tau^*$  of types  $\tau$  given by

$$\begin{aligned} \theta^* = \neg\neg\theta \ (\theta \in T), \quad 1^* = 1, \quad (\tau_1 \times \tau_2)^* = \tau_1^* \times \tau_2^*, \quad (\tau_1 \rightarrow \tau_2)^* = \tau_1^* \rightarrow \tau_2^*, \\ 0^* = 0, \quad (\tau_1 + \tau_2)^* = \neg(\neg\tau_1^* \times \neg\tau_2^*) \end{aligned}$$

and the following facts:

- (i) For every type  $\tau$  and every interpretation  $\mathcal{I}$  of base types in  $\mathbf{F}$ , the following hold:

$$\mathcal{I}[\tau^*] \cong 0 \text{ or } \mathcal{I}[\tau^*] \cong 1$$

and

$$\begin{aligned} \mathcal{I}[\tau^*] \cong 1 &\iff \overline{\tau^*} \text{ is a classical tautology} \\ &\iff \overline{\tau^*} \text{ is an intuitionistic tautology.} \end{aligned}$$

(ii) For every type  $\tau$ , the formula  $\overline{\tau^*} \leftrightarrow \neg\neg\overline{\tau}$  is an intuitionistic tautology.

Indeed, assuming (3) it follows using (i) that  $(\overline{\tau_1^*} \rightarrow \overline{\tau_2^*}) = \overline{(\tau_1 \rightarrow \tau_2)^*}$  is an intuitionistic tautology. Thus, we have from (ii) that  $\neg\neg\overline{\tau_1} \rightarrow \neg\neg\overline{\tau_2}$  is an intuitionistic tautology, from which we conclude that so is  $\neg\overline{\tau_2} \rightarrow \neg\overline{\tau_1}$ . Analogously, one sees that  $\neg\overline{\tau_1} \rightarrow \neg\overline{\tau_2}$  is also an intuitionistic tautology, and we are done.  $\square$

It follows that the problem of whether two *negated* types are isomorphic in the theory of BiCCCs is decidable.

**Corollary 2.8.** *For all types  $\tau$  in  $\mathcal{F}_{0,+}[T]$  and arithmetic expressions  $e$  with  $\overline{e} = \tau$ ,*

$$\tau \cong 0 \text{ in } \mathcal{F}_{0,+}[T] \iff \mathbf{F} \models \tau = 0 \iff N_0 \models e = 0.$$

### 3. Concluding remarks

The results of this paper are the first significant advance in the study of type isomorphisms in the presence of empty and sum types. Many questions still remain open, for instance whether there are arithmetic equations in the language of  $1, \cdot, \uparrow, 0$  or of  $1, \cdot, \uparrow, +$  that do not correspond to type isomorphisms. We conjecture that Gurevič's result [19] for establishing the non-finite axiomatisability of the equational theory of the model of positive natural numbers  $\langle N, 1, \cdot, \uparrow, + \rangle$  can be generalised to the case of the model of natural numbers  $\langle N_0, 1, 0, \cdot, \uparrow, + \rangle$ , and hence, by the results of this paper, that the equational theory of type isomorphism in bicartesian closed categories is not finitely axiomatisable. Decidability questions of the equational theory of type isomorphisms in the extensions of the typed lambda calculus with empty and/or sum types should be addressed. Finally, the observations in Section 2.3 suggest that the appropriate framework for characterising the type isomorphisms that hold in the category of finite sets for types with arrow, empty and sum constructors may be calculi for classical or intermediate logics.

### Acknowledgements

We are grateful to Claude Kirchner and Sergei Soloviev for interesting discussions on the subject, and to Alex Simpson for pointing out (10). The first author's research was supported by an EPSRC Advanced Research Fellowship.

### Appendix A. Proof of Lemma 2.5

For the following definitions (where, to improve readability, all type information has been omitted):

$$\begin{aligned} t[\varphi, \phi, \varepsilon, \epsilon] &\stackrel{\text{def}}{=} \lambda h. \langle p[\varphi, \phi, \varepsilon, \pi_1 h, \pi_2 h], p[\phi, \varphi, \varepsilon, \pi_2 h, \pi_1 h] \rangle \\ p[\varphi, \phi, \gamma, f, g] &\stackrel{\text{def}}{=} \lambda y. \delta( g(y), \\ &\quad g_1. \iota_1(\lambda x. F[\phi, \gamma, f, g_1, x, y]), \\ &\quad g_2. \iota_2(\lambda x. G[\varphi, \gamma, f, g_2, x, y]) \\ F[\phi, \gamma, f, g, x, y] &\stackrel{\text{def}}{=} \delta( f(\pi_2(\gamma(x, y))), \\ &\quad f_1. f_1(\pi_1(\gamma(x, y))), \\ &\quad f_2. \pi_1(\phi(g(x), f_2(\pi_1(\gamma(x, y)))))) \\ G[\varphi, \gamma, f, g, x, y] &\stackrel{\text{def}}{=} \delta( f(\pi_2(\gamma(x, y))), \\ &\quad f_1. \pi_2(\varphi(f_1(\pi_1(\gamma(x, y))), g(x))), \\ &\quad f_2. f_2(\pi_1(\gamma(x, y)))) \end{aligned}$$

we will establish the identity

$$\lambda h. t[\varphi, \phi, \varepsilon, \varepsilon](t[\varphi, \phi, \varepsilon, \varepsilon](h)) = \lambda h. h$$

in the equational theory of the typed lambda calculus with empty and sum types (see Fig. 3).

The identities (A)–(G) below, all of which are valid in the equational theory, will be used throughout the proof.

- (A)  $\delta(\delta(t_0, x_1. t_1, x_2. t_2), y_1. u_1, y_2. u_2)$   
 $= \delta(t_0, x_1. \delta(t_1, y_1. u_1, y_2. u_2), x_2. \delta(t_2, y_1. u_1, y_2. u_2))$
- (B)  $\delta(t_0, x_1. \delta(t_0, y_1. t_1, y_2. t_2), x_2. t) = \delta(t_0, x_1. t_1[x_1^1/y_1], x_2. t)$   
 $\delta(t_0, x_1. t, x_2. \delta(t_0, y_1. t_1, y_2. t_2)) = \delta(t_0, x_1. t_1, x_2. t_2[x_2^2/y_2])$
- (C)  $\delta(t_0, x_1. \delta(u_0, y_1. u_1, y_2. u_2), x_2. t_2)$   
 $= \delta(u_0, y_1. \delta(t_0, x_1. u_1, x_2. t_2), y_2. \delta(t_0, x_1. u_2, x_2. t_2))$   
 $\delta(t_0, x_1. t_1, x_2. \delta(u_0, y_1. u_1, y_2. u_2))$   
 $= \delta(u_0, y_1. \delta(t_0, x_1. t_1, x_2. u_1), y_2. \delta(t_0, x_1. t_1, x_2. u_2))$
- (D)  $\lambda x. \delta(t_0, x_1. t_1, x_2. t_2) = \delta(t_0, x_1. \lambda x. t_1, x_2. \lambda x. t_2) \quad (x \notin \text{FV}(t_0) \cup \{x_1, x_2\})$
- (E)  $t(\delta(t_0, x_1. t_1, x_2. t_2)) = \delta(t_0, x_1. t(t_1), x_2. t(t_2)) \quad (x_1, x_2 \notin \text{FV}(t))$
- (F)  $\langle \delta(t_0, x_1. t_1, x_2. t_2), t \rangle = \delta(t_0, x_1. \langle t_1, t \rangle, x_2. \langle t_2, t \rangle)$   
 $\langle t, \delta(t_0, x_1. t_1, x_2. t_2) \rangle = \delta(t_0, x_1. \langle t, t_1 \rangle, x_2. \langle t, t_2 \rangle) \quad (x_1, x_2 \notin \text{FV}(t))$
- (G)  $\delta(t_0, x_1. t, x_2. t) = t \quad (x_1, x_2 \notin \text{FV}(t)).$

We start the proof by observing that

$$t[\varphi, \phi, \varepsilon, \varepsilon](t[\varphi, \phi, \varepsilon, \varepsilon](h)) = \langle p[\varphi, \phi, \varepsilon, p[\varphi, \phi, \varepsilon, \pi_1 h, \pi_2 h]], p[\phi, \varphi, \varepsilon, \pi_2 h, \pi_1 h]], \\ p[\phi, \varphi, \varepsilon, p[\phi, \varphi, \varepsilon, \pi_2 h, \pi_1 h]], p[\varphi, \phi, \varepsilon, \pi_1 h, \pi_2 h]] \rangle$$

and show that the first and second components of the above pair are the respective projections of  $h$ ; i.e., that

$$p[\varphi, \phi, \varepsilon, p[\varphi, \phi, \varepsilon, \pi_1 h, \pi_2 h]], p[\phi, \varphi, \varepsilon, \pi_2 h, \pi_1 h]] = \pi_1 h, \\ p[\phi, \varphi, \varepsilon, p[\phi, \varphi, \varepsilon, \pi_2 h, \pi_1 h]], p[\varphi, \phi, \varepsilon, \pi_1 h, \pi_2 h]] = \pi_2 h.$$

To this end it will be enough to establish

$$(1) \quad p[\varphi, \phi, \varepsilon, p[\varphi, \phi, \varepsilon, f, g]], p[\phi, \varphi, \varepsilon, g, f]] = f.$$

The left hand side of (1) equals

$$(2) \quad \lambda y. \delta(p[\phi, \varphi, \varepsilon, g, f](y), \\ g_1. \iota_1(\lambda x. F[\phi, \varepsilon, p[\varphi, \phi, \varepsilon, f, g], g_1, x, y]), \\ g_2. \iota_2(\lambda x. G[\varphi, \varepsilon, p[\varphi, \phi, \varepsilon, f, g], g_2, x, y]))$$

and, as the discriminator of (2) equals

$$(3) \quad \delta(f(y), \\ g'_1. \iota_1(\lambda x'. F[\varphi, \varepsilon, g, g'_1, x', y]), \\ g'_2. \iota_2(\lambda x'. G[\phi, \varepsilon, g, g'_2, x', y]))$$

we have, from (2) and (3) using (A), that the left hand side of (1) equals

$$(4) \quad \lambda y. \delta(f(y), \\ g'_1. \iota_1(\lambda x. F[\phi, \varepsilon, p[\varphi, \phi, \varepsilon, f, g], \lambda x'. F[\varphi, \varepsilon, g, g'_1, x', y], x, y]), \\ g'_2. \iota_2(\lambda x. G[\varphi, \varepsilon, p[\varphi, \phi, \varepsilon, f, g], \lambda x'. G[\phi, \varepsilon, g, g'_2, x', y], x, y]))$$

We now calculate, in turn, the following terms appearing in the conditional branches of (4):

- (5)  $F[\phi, \varepsilon, p[\varphi, \phi, \varepsilon, f, g], \lambda x'. F[\varphi, \varepsilon, g, g'_1, x', y], x, y],$   
(6)  $G[\varphi, \varepsilon, p[\varphi, \phi, \varepsilon, f, g], \lambda x'. G[\phi, \varepsilon, g, g'_2, x', y], x, y].$

The term (5) equals

$$(7) \quad \delta( p[\varphi, \phi, \epsilon, f, g](\pi_2(\epsilon(x, y))), \\ f_1. f_1(\pi_1(\epsilon(x, y))), \\ f_2. \pi_1(\phi( F[\varphi, \epsilon, g, g'_1, x, y], f_2(\pi_1(\epsilon(x, y))) ) ) )$$

and, as the discriminator of (7) equals

$$(8) \quad \delta( g(\pi_2(\epsilon(x, y))), \\ g'_1. \iota_1(\lambda x''. F[\phi, \epsilon, f, g'_1, x'', \pi_2(\epsilon(x, y))]), \\ g'_2. \iota_2(\lambda x''. G[\varphi, \epsilon, f, g'_2, x'', \pi_2(\epsilon(x, y))]) )$$

we have, from (7) and (8) using (A), that (5) equals

$$(9) \quad \delta( g(\pi_2(\epsilon(x, y))), \\ g'_1. F[\phi, \epsilon, f, g'_1, \pi_1(\epsilon(x, y)), \pi_2(\epsilon(x, y))], \\ g'_2. \pi_1(\phi( F[\varphi, \epsilon, g, g'_1, x, y], G[\varphi, \epsilon, f, g'_2, \pi_1(\epsilon(x, y)), \pi_2(\epsilon(x, y))] ) ) ) .$$

We calculate, in turn, the following terms appearing in the conditional branches of (9):

$$(10) \quad F[\phi, \epsilon, f, g'_1, \pi_1(\epsilon(x, y)), \pi_2(\epsilon(x, y))],$$

$$(11) \quad G[\varphi, \epsilon, f, g'_2, \pi_1(\epsilon(x, y)), \pi_2(\epsilon(x, y))].$$

The term (10) equals

$$\delta( f(\pi_2(\epsilon(\pi_1(\epsilon(x, y))), \pi_2(\epsilon(x, y)) ) ) , \\ f_1. f_1(\pi_1(\epsilon(\pi_1(\epsilon(x, y))), \pi_2(\epsilon(x, y)) ) ) , \\ f_2. \pi_1(\phi( g'_1(\pi_1(\epsilon(x, y))), f_2(\pi_1(\epsilon(\pi_1(\epsilon(x, y))), \pi_2(\epsilon(x, y)) ) ) ) ) )$$

from which, applying the surjective-pairing law  $\langle \pi_1(z), \pi_2(z) \rangle = z$  three times, we obtain

$$\delta( f(\pi_2(\epsilon(x, y))), \\ f_1. f_1(\pi_1(\epsilon(x, y)) ) , \\ f_2. \pi_1(\phi( g'_1(\pi_1(\epsilon(x, y))), f_2(\pi_1(\epsilon(x, y)) ) ) ) .$$

Further, since  $\epsilon$  and  $\epsilon$  are mutual inverses, after an application of the first-projection law  $\pi_1(\langle z_1, z_2 \rangle) = z_1$ , we get that this term equals the following one:

$$(12) \quad \delta( f(y), \\ f_1. f_1(x), \\ f_2. \pi_1(\phi( g'_1(\pi_1(\epsilon(x, y))), f_2(x) ) ) ) .$$

On the other hand, the term (11) equals

$$\delta( f(\pi_2(\epsilon(\pi_1(\epsilon(x, y))), \pi_2(\epsilon(x, y)) ) ) , \\ f_1. \pi_2(\phi( f_1(\pi_1(\epsilon(\pi_1(\epsilon(x, y))), \pi_2(\epsilon(x, y)) ) ) , g'_2(\pi_1(\epsilon(x, y))) ) ) , \\ f_2. f_2(\pi_1(\epsilon(\pi_1(\epsilon(x, y))), \pi_2(\epsilon(x, y)) ) ) )$$

which equals

$$(13) \quad \delta( f(y), \\ f_1. \pi_2(\phi( f_1(x), g'_2(\pi_1(\epsilon(x, y))) ) ) , \\ f_2. f_2(x) ) .$$

Thus, from (4), (9), (12), and (13), the left hand side of (1) equals

$$\begin{aligned}
& \lambda y. \delta( f(y), \\
& \quad g'_1. \iota_1( \lambda x. \delta( g(\pi_2(\varepsilon(x, y))), \\
& \quad \quad g''_1. \delta( f(y), \\
& \quad \quad \quad f_1. f_1(x), \\
& \quad \quad \quad f_2. \pi_1( \phi( g'_1(\pi_1(\varepsilon(x, y))), f_2(x) ) ) ), \\
& \quad g''_2. \pi_1( \phi( \delta( g(\pi_2(\varepsilon(x, y))), \\
& \quad \quad f_1. f_1(\pi_1(\varepsilon(x, y))), \\
& \quad \quad f_2. \pi_1( \phi( g'_1(x), f_2(\pi_1(\varepsilon(x, y))) ) ) ) ), \\
& \quad \delta( f(y), \\
& \quad \quad f_1. \pi_2( \phi( f_1(x), g''_2(\pi_1(\varepsilon(x, y))) ) ), \\
& \quad \quad f_2. f_2(x) ) ) ) ) ), \\
& g'_2. \iota_2( \lambda x. G[\varphi, \varepsilon, p[\varphi, \phi, \varepsilon, f, g], \lambda x'. G[\phi, \varepsilon, g, g'_2, x', y], x, y] ) )
\end{aligned}$$

which, using (B)–(F), equals

$$\begin{aligned}
& \lambda y. \delta( f(y), \\
& \quad g'_1. \iota_1( \lambda x. \delta( g(\pi_2(\varepsilon(x, y))), \\
& \quad \quad g'_1. g'_1(x), \\
& \quad \quad g''_2. \pi_1( \phi( \pi_1( \phi( g'_1(x), g''_2(\pi_1(\varepsilon(x, y))) ) ) ), \\
& \quad \quad \quad \pi_2( \phi( g'_1(x), g''_2(\pi_1(\varepsilon(x, y))) ) ) ) ) ) ), \\
& \quad g'_2. \iota_2( \lambda x. G[\varphi, \varepsilon, p[\varphi, \phi, \varepsilon, f, g], \lambda x'. G[\phi, \varepsilon, g, g'_2, x', y], x, y] ) )
\end{aligned}$$

and that, using surjective pairing, the fact that  $\varphi$  and  $\phi$  are mutual inverses, the first-projection law, the equation (G), and the extensionality law  $\lambda z. t(z) = t(z \notin \text{FV}(t))$ , further equals

$$\begin{aligned}
(14) \quad & \lambda y. \delta( f(y), \\
& \quad g'_1. \iota_1(g'_1), \\
& \quad g'_2. \iota_2( \lambda x. G[\varphi, \varepsilon, p[\varphi, \phi, \varepsilon, f, g], \lambda x'. G[\phi, \varepsilon, g, g'_2, x', y], x, y] ) ) ).
\end{aligned}$$

We now calculate (6), which appears in the second branch above. This term equals

$$\begin{aligned}
& \delta( p[\varphi, \phi, \varepsilon, f, g](\pi_2(\varepsilon(x, y))), \\
& \quad f'_1. \pi_2( \phi( f'_1(\pi_1(\varepsilon(x, y))), G[\phi, \varepsilon, g, g'_2, x, y] ) ), \\
& \quad f'_2. f'_2(\pi_1(\varepsilon(x, y))) )
\end{aligned}$$

and from this and (8), using (A), it further equals

$$\begin{aligned}
& \delta( g(\pi_2(\varepsilon(x, y))), \\
& \quad g'_1. \pi_2( \phi( F[\phi, \varepsilon, f, g'_1, \pi_1(\varepsilon(x, y)), \pi_2(\varepsilon(x, y))], \\
& \quad \quad G[\phi, \varepsilon, g, g'_2, x, y] ) ), \\
& \quad g''_2. G[\varphi, \varepsilon, f, g'_2, \pi_1(\varepsilon(x, y)), \pi_2(\varepsilon(x, y))] )
\end{aligned}$$

which, from (12) and (13), equals

$$\begin{aligned}
(15) \quad & \delta( g(\pi_2(\varepsilon(x, y))), \\
& g_1'' \cdot \pi_2(\varphi( \delta( f(y), \\
& \quad f_1 \cdot f_1(x), \\
& \quad f_2 \cdot \pi_1(\phi( g_1''(\pi_1(\varepsilon(x, y))), f_2(x) ) ) ), \\
& \delta( g(\pi_2(\varepsilon(x, y))), \\
& \quad f_1 \cdot \pi_2(\phi( f_1(\pi_1(\varepsilon(x, y))), g_2'(x) ) ), \\
& \quad f_2 \cdot f_2(\pi_1(\varepsilon(x, y))) ) ) ), \\
& g_2'' \cdot \delta( f(y), \\
& \quad f_1 \cdot \pi_2(\varphi( f_1(x), g_2''(\pi_1(\varepsilon(x, y))) ) ), \\
& \quad f_2 \cdot f_2(x) ) ).
\end{aligned}$$

Thus, from (14) and (15), the left hand side of (1) equals

$$\begin{aligned}
& \lambda y. \delta( f(y), \\
& \quad g_1' \cdot \iota_1(g_1'), \\
& \quad g_2' \cdot \iota_2(\lambda x. \delta( g(\pi_2(\varepsilon(x, y))), \\
& \quad \quad g_1'' \cdot \pi_2(\varphi( \delta( f(y), \\
& \quad \quad \quad f_1 \cdot f_1(x), \\
& \quad \quad \quad f_2 \cdot \pi_1(\phi( g_1''(\pi_1(\varepsilon(x, y))), f_2(x) ) ) ), \\
& \quad \quad \delta( g(\pi_2(\varepsilon(x, y))), \\
& \quad \quad \quad f_1 \cdot \pi_2(\phi( f_1(\pi_1(\varepsilon(x, y))), g_2'(x) ) ), \\
& \quad \quad \quad f_2 \cdot f_2(\pi_1(\varepsilon(x, y))) ) ) ), \\
& \quad g_2'' \cdot \delta( f(y), \\
& \quad \quad f_1 \cdot \pi_2(\varphi( f_1(x), g_2''(\pi_1(\varepsilon(x, y))) ) ), \\
& \quad \quad f_2 \cdot f_2(x) ) ) ) )
\end{aligned}$$

which, using (B)–(F), equals

$$\begin{aligned}
& \lambda y. \delta( f(y), \\
& \quad g_1' \cdot \iota_1(g_1'), \\
& \quad g_2' \cdot \iota_2(\lambda x. \delta( g(\pi_2(\varepsilon(x, y))), \\
& \quad \quad g_1'' \cdot \pi_2(\varphi( \pi_1(\phi( g_1''(\pi_1(\varepsilon(x, y))), g_2'(x) ) ), \\
& \quad \quad \quad \pi_2(\phi( g_1''(\pi_1(\varepsilon(x, y))), g_2'(x) ) ) ) ), \\
& \quad \quad g_2'' \cdot g_2'(x) ) ) ).
\end{aligned}$$

By surjective pairing, this is equal to

$$\begin{aligned}
& \lambda y. \delta( f(y), \\
& \quad g_1' \cdot \iota_1(g_1'), \\
& \quad g_2' \cdot \iota_2(\lambda x. \delta( g(\pi_2(\varepsilon(x, y))), \\
& \quad \quad g_1'' \cdot \pi_2(\varphi( \phi( g_1''(\pi_1(\varepsilon(x, y))), g_2'(x) ) ) ) \\
& \quad \quad g_2'' \cdot g_2'(x) ) ) ).
\end{aligned}$$

Moreover, as  $\phi$  and  $\varphi$  are mutual inverses, an application of the second-projection law on the second branch yields

$$\begin{aligned}
& \lambda y. \delta( f(y), \\
& \quad g_1' \cdot \iota_1(g_1'), \\
& \quad g_2' \cdot \iota_2(\lambda x. \delta(g(\pi_2(\varepsilon(x, y))), g_1'' \cdot g_2'(x), g_2'' \cdot g_2'(x) ) ) )
\end{aligned}$$

which, by (G) and the extensionality law, equals

$$\lambda y. \delta( f(y) , g'_1 \cdot \iota_1(g'_1) , g'_2 \cdot \iota_2(g'_2) ).$$

Finally, by the weak sum-extensionality law  $\delta(t, z_1 \cdot \iota_1(z_1), z_2 \cdot \iota_2(z_2)) = t$  and the extensionality law, this is equal to  $f$  as required.

Hence, the identity (1) is established.
