#### Abstract

We prove that, for a smooth complete variety X over a perfect field,

 $H^{i}(X, \mathbb{Z}_{p}(r)) \cong \operatorname{Hom}_{\mathbb{D}^{b}_{a}(R)}(\mathbb{1}, R\Gamma(W\Omega^{\bullet}_{X})(r)[i]),$ 

where  $H^i(X, \mathbb{Z}_p(r)) = \lim_{\substack{\leftarrow n \\ n}} H^{i-r}(X_{\text{et}}, v_n(r))$  (Amer. J. Math. 108 (2) (1986) 297–360),  $W\Omega^{\bullet}_X$  is the de Rham–Witt complex on X (Ann. Scient. Ec. Num. Sup. 12 (1979b) 501–661), and  $D^b_c(R)$  is the triangulated category of coherent complexes over the Raynaud ring (Inst. Hautes. Etuder Sci. Publ. Math. 57 (1983) 73–212). © 2005 Published by Elsevier Inc.

#### 1. Introduction

According to the standard philosophy (cf. [2, 3.1]), a cohomology theory  $X \mapsto H^i(X, r)$  on the algebraic varieties over a fixed field k should arise from a functor  $R\Gamma$  taking values in a triangulated category D equipped with a t-structure and a Tate twist  $D \mapsto D(r)$  (a self-equivalence). The heart  $D^{\heartsuit}$  of D should be stable under the Tate twist and have a tensor structure; in particular, there should be an essentially unique identity object 1 in  $D^{\heartsuit}$  such that  $1 \otimes D \cong D \cong D \otimes 1$  for all objects in  $D^{\heartsuit}$ . The cohomology theory should satisfy

$$H^{i}(X, r) \cong \operatorname{Hom}_{\mathsf{D}}(1, R\Gamma(X)(r)[i]).$$
(1)

For example, motivic cohomology  $H^i_{\text{mot}}(X, \mathbb{Q}(r))$  should arise in this way from a functor to a category D whose heart is the category of mixed motives k. Absolute  $\ell$ -adic étale cohomology  $H^i_{\text{et}}(X, \mathbb{Z}_{\ell}(r)), \ell \neq \text{char}(k)$ , arises in this way from a functor to a category D whose heart is the category of continuous representations of  $\text{Gal}(\bar{k}/k)$  on finitely generated  $\mathbb{Z}_{\ell}$ -modules [5]. When k is algebraically closed,  $H^i_{\text{et}}(X, \mathbb{Z}_{\ell}(r))$  becomes the familiar group  $\lim_{\leftarrow} H^i_{\text{et}}(X, \mu_{\ell^n}^{\otimes r})$  and lies in  $D^{\heartsuit}$ ; moreover, in this case, (1) simplifies to

$$H^{i}(X,r) \cong H^{i}(R\Gamma(X)(r)).$$
<sup>(2)</sup>

Now let k be a perfect field of characteristic  $p \neq 0$ , and let W be the ring of Witt vectors over k. For a smooth complete variety X over k, let  $W\Omega_X^{\bullet}$  denote the de Rham-Witt complex of Bloch-Deligne-Illusie (see [10]). Regard  $\Gamma = \Gamma(X, -)$  as a functor from sheaves of W-modules on X to W-modules. Then

$$H^i_{\operatorname{crys}}(X/W) \cong H^i(R\Gamma(W\Omega^{\bullet}_X))$$

[9, 3.4.3], where  $H^i_{crys}(X/W)$  is the crystalline cohomology of X [1]. In other words,  $X \mapsto H^i_{crys}(X/W)$  arises as in (2) from the functor  $X \mapsto R\Gamma(W\Omega^{\bullet}_X)$  with values in  $D^+(W)$ .

Let *R* be the Raynaud ring, let D(X, R) be the derived category of the category of sheaves of graded *R*-modules on *X*, and let D(R) be the derived category of the category of graded *R*-modules [11, 2.1]. Then  $\Gamma$  derives to a functor

$$R\Gamma: \mathsf{D}(X, R) \to \mathsf{D}(R).$$

When we regard  $W\Omega_X^{\bullet}$  as a sheaf of graded *R*-modules on *X*,  $R\Gamma(W\Omega_X^{\bullet})$  lies in the full subcategory  $D_c^b(R)$  of D(R) consisting of coherent complexes [12, II 2.2], which Ekedahl has shown to be a triangulated subcategory with *t*-structure [11, 2.4.8]. In this

note, we define a Tate twist (r) on  $D_c^b(R)$  and prove that

$$H^{i}(X, \mathbb{Z}_{p}(r)) \cong \operatorname{Hom}_{\mathsf{D}^{b}_{\mathcal{O}}(R)}(\mathbb{1}, R\Gamma(W\Omega^{\bullet}_{X})(r)[i]).$$

Here  $H^i(X, \mathbb{Z}_p(r)) =_{df} \lim_{\substack{\leftarrow n \\ et}} H^{i-r}_{et}(X, v_n(r))$  with  $v_n(r)$  the additive subsheaf of  $W_n \Omega_X^r$ locally generated for the étale topology by the logarithmic differentials [14, §1], and  $\mathbb{1}$ is the identity object for the tensor structure on graded *R*-modules defined by Ekedahl [11, 2.6.1]. In other words,  $X \mapsto H^i(X, \mathbb{Z}_p(r))$  arises as in (1) from the functor  $X \mapsto R\Gamma(W\Omega_X^{\bullet})$  with values in  $D_c^b(R)$ .

This result is used in the construction of the triangulated category of integral motives in [16].

It is a pleasure for us to be able to contribute to this volume: the  $\mathbb{Z}_p$ -cohomology was introduced (in primitive form) by the first author in an article whose main purpose was to prove a conjecture of Artin, and, for the second author, Artin's famous 18.701-2 course was his first introduction to real mathematics.

#### 2. The Tate twist

According to the standard philosophy, the Tate twist on motives should be  $N \mapsto N(r) = N \otimes \mathbb{T}^{\otimes r}$  with  $\mathbb{T}$  dual to  $\mathbb{L}$  and  $\mathbb{L}$  defined by  $Rh(\mathbb{P}^1) = \mathbb{1} \oplus \mathbb{L}[-2]$ .

The Raynaud ring is the graded W-algebra  $R = R^0 \oplus R^1$  generated by F and V in degree 0 and d in degree 1, subject to the relations FV = p = VF,  $Fa = \sigma a \cdot F$ ,  $aV = V \cdot \sigma a$ , ad = da ( $a \in W$ ),  $d^2 = 0$ , and FdV = d; in particular,  $R^0$  is the Dieudonné ring  $W_{\sigma}[F, V]$  [11, 2.1]. A graded *R*-module is nothing more than a complex

$$M^{\bullet} = (\dots \to M^i \xrightarrow{d} M^{i+1} \to \dots)$$

of *W*-modules whose components  $M^i$  are modules over  $R^0$  and whose differentials *d* satisfy FdV = d. We define *T* to be the functor of graded *R*-modules such that  $(TM)^i = M^{i+1}$  and T(d) = -d. It is exact and defines a self-equivalence  $T : D_c^b(R) \to D_c^b(R)$ .

The identity object for Ekedahl's tensor structure on the graded R-modules is the graded R-module

$$\mathbb{1} = (W, F = \sigma, V = p\sigma^{-1})$$

concentrated in degree zero [11, 2.6.1.3]. It is equal to the module  $E_{0/1} =_{df} R^0/(F-1)$  of Ekedahl [3, p. 66].

There is a canonical homomorphism

$$\mathbb{1} \oplus T^{-1}(\mathbb{1})[-1] \to R\Gamma(W\Omega^{\bullet}_{\mathbb{D}^1})$$

(in  $D_c^b(R)$ ), which is an isomorphism because it is on  $W_1\Omega_{\mathbb{P}^1}^{\bullet} = \Omega_{\mathbb{P}^1}^{\bullet}$  and we can apply Ekedahl's "Nakayama lemma" [11, 2.3.7]. See [8, I 4.1.11, p. 21], for a more general statement. This suggests our definition of the Tate twist *r* (for  $r \ge 0$ ), namely, we set

$$M(r) = T^r(M)[-r]$$

for *M* in  $D_c^b(R)$ .

Ekedahl has defined a nonstandard *t*-structure on  $D_c^b(R)$  the objects of whose heart  $\Delta$  are called diagonal complexes [11, 6.4]. It will be important for our future work to note that  $\mathbb{T} = T(\mathbb{1})[-1]$  is a diagonal complex: the sum of its module degree (-1) and complex degree (+1) is zero. The Tate twist is an exact functor which defines a self-equivalence of  $D_c^b(R)$  preserving  $\Delta$ .

# 3. Theorem and corollaries

Regard  $W\Omega_X^{\bullet}$  as a sheaf of graded *R*-modules on *X*, and write  $R\Gamma$  for the functor  $D(X, R) \to D(R)$  defined by  $\Gamma(X, -)$ . As we noted above,  $R\Gamma(W\Omega_X^{\bullet})$  lies in  $D_c^b(R)$ .

**Theorem.** For any smooth complete variety X over a perfect field k of characteristic  $p \neq 0$ , there is a canonical isomorphism

$$H^{i}(X, \mathbb{Z}_{p}(r)) \cong \operatorname{Hom}_{\mathsf{D}^{b}_{c}(R)}(\mathbb{1}, R\Gamma(W\Omega^{\bullet}_{X})(r)[i]).$$

**Proof.** For a graded *R*-module  $M^{\bullet}$ ,

$$\operatorname{Hom}(\mathbb{1}, M^{\bullet}) = \operatorname{Ker}(1 - F: M^0 \to M^0).$$

To obtain a similar expression in  $D^b(R)$  we argue as in Ekedahl [3, p. 90]. Let  $\hat{R}$  denote the completion  $\lim_{\leftarrow} R/(V^n R + dV^n R)$  of R [3, p. 60]. Then right multiplication by 1 - F is injective, and  $1 \cong \hat{R}^0/\hat{R}^0(1 - F)$ . As F is topologically nilpotent on  $\hat{R}^1$ , this shows that the sequence

$$0 \longrightarrow \hat{R} \xrightarrow{(1-F)} \hat{R} \longrightarrow 1 \longrightarrow 0, \tag{3}$$

is exact. Thus, for a complex of graded *R*-modules *M* in  $D^b(R)$ ,

$$\operatorname{Hom}_{\mathsf{D}(R)}(\mathbb{1},M) \stackrel{[7,10.9]}{\cong} H^0(R\operatorname{Hom}(\mathbb{1},M)) \stackrel{(3)}{\cong} H^0(R\operatorname{Hom}(\hat{R} \stackrel{\cdot(1-F)}{\longrightarrow} \hat{R},M)).$$

If *M* is complete in the sense of Illusie 1983, 2.4, then  $R \operatorname{Hom}(\hat{R}, M) \cong R \operatorname{Hom}(R, M)$ [3, 5.9.3ii, p. 78], and so

$$\operatorname{Hom}_{\mathsf{D}(R)}(\mathbb{1}, M) \cong H^{0}(\operatorname{Hom}(R \xrightarrow{(1-F)} R, M))$$
$$\cong H^{0}(\operatorname{Hom}(R, M) \xrightarrow{1-F} \operatorname{Hom}(R, M)). \tag{4}$$

Following Illusie [11, 2.1], we shall view a complex of graded *R*-modules as a bicomplex  $M^{\bullet\bullet}$  in which the first index corresponds to the *R*-grading: thus the  $j^{\text{th}}$  row  $M^{\bullet j}$  of the bicomplex is the *R*-module ( $\cdots \rightarrow M^{i,j} \rightarrow M^{i+1,j} \rightarrow \cdots$ ), and the  $i^{\text{th}}$  column  $M^{i\bullet}$  is a complex of (ungraded)  $R^0$ -modules. The *j*th-cohomology  $H^j(M^{\bullet\bullet})$  of  $M^{\bullet\bullet}$  is the graded *R*-module

$$(\cdots \to H^j(M^{i\bullet}) \to H^j(M^{i+1\bullet}) \to \cdots).$$

Now,  $\operatorname{Hom}(R, M^{\bullet \bullet}) = M^{0 \bullet}$ , and so

$$H^{0}(\operatorname{Hom}(R, M^{\bullet\bullet}(r)[i])) = H^{i-r}(M^{r\bullet}).$$
(5)

The complex of graded *R*-modules  $R\Gamma(W\Omega_X^{\bullet})$  is complete [11, 2.4, Example (b), p. 33], and so (4) gives an isomorphism

$$\operatorname{Hom}_{\mathsf{D}(R)}(\mathbb{1}, R\Gamma(W\Omega^{\bullet}_{X})(r)[i]) \xrightarrow{1-F} \operatorname{Hom}(R, R\Gamma(W\Omega^{\bullet}_{X})(r)[i]) \xrightarrow{1-F} \operatorname{Hom}(R, R\Gamma(W\Omega^{\bullet}_{X})(r)[i])).$$
(6)

The *j*th-cohomology of  $R\Gamma(W\Omega_X^{\bullet})$  is obviously

$$H^{j}(R\Gamma(W\Omega_{X}^{\bullet})) = (\cdots \to H^{j}(X, W\Omega_{X}^{i}) \to H^{j}(X, W\Omega_{X}^{i+1}) \to \cdots)$$

[11, 2.2.1], and so (5) allows us to rewrite (6) as

$$\operatorname{Hom}_{\mathsf{D}(R)}(\mathbb{1}, R\Gamma(W\Omega_X^{\bullet})(r)[i]) \cong H^{i-r}(R\Gamma(W\Omega_X^r) \xrightarrow{1-r} R\Gamma(W\Omega_X^r)).$$

This gives an exact sequence

$$\dots \to \operatorname{Hom}(\mathbb{1}, R\Gamma(W\Omega_X^{\bullet})(r)[i]) \to H^{i-r}(X, W\Omega_X^r) \xrightarrow{1-F} H^{i-r}(X, W\Omega_X^r) \to \dots$$
(7)

On the other hand, there is an exact sequence [10, I 5.7.2]

$$0 \to v_{\bullet}(r) \to W_{\bullet}\Omega^r_X \xrightarrow{1-F} W_{\bullet}\Omega^r_X \to 0$$

of prosheaves on  $X_{et}$ , which gives rise to an exact sequence

$$\dots \to H^{i}(X, \mathbb{Z}_{p}(r)) \to H^{i-r}(X, W_{\bullet}\Omega^{r}_{X}) \xrightarrow{1-F} H^{i-r}(X, W_{\bullet}\Omega^{r}_{X}) \to \dots$$
(8)

[14, 1.10]. Here  $v_{\bullet}(r)$  denotes the projective system  $(v_n(r))_{n \ge 0}$ , and  $H^i(X, W_{\bullet}\Omega_X^r)$ =  $\lim_{\leftarrow} H^i(X, W_n\Omega_X^r)$  (étale or Zariski cohomology—they are the same).

Since  $H^r(X, W\Omega_X^r) \cong H^r(X, W_{\bullet}\Omega_X^r)$  [9, 3.4.2, p. 101], the sequences (7) and (8) will imply the theorem once we check that there is a suitable map from one sequence to the other, but the right hand square in

gives rise to such a map.  $\Box$ 

As in Milne [14, p. 309], we let  $H^{i}(X, (\mathbb{Z}/p^{n}\mathbb{Z})(r)) = H^{i-r}_{\text{et}}(X, v_{n}(r)).$ 

Corollary 1. There is a canonical isomorphism

$$H^{i}(X, (\mathbb{Z}/p^{n}\mathbb{Z})(r)) \cong \operatorname{Hom}_{D^{b}_{c}(R)}(\mathbb{1}, R\Gamma W_{n}\Omega^{\bullet}_{X}(r)[i]).$$

**Proof.** The canonical map  $v_{\bullet}(r)/p^n v_{\bullet}(r) \rightarrow v_n(r)$  is an isomorphism [10, I 5.7.5, p. 598], and the canonical map  $W\Omega_X^{\bullet}/p^n W\Omega_X^{\bullet} \rightarrow W_n \Omega_X^{\bullet}$  is a quasi-isomorphism [10, I 3.17.3, p. 577]. The corollary now follows from the theorem by an obvious five-lemma argument.  $\Box$ 

Lichtenbaum [13] conjectures the existence of a complex  $\mathbb{Z}(r)$  on  $X_{\text{et}}$  satisfying certain axioms and sets  $H^i_{\text{mot}}(X, r) = H^i_{\text{et}}(X, \mathbb{Z}(r))$ . Milne [15, p. 68] adds the "Kummer *p*-sequence" axiom that there be an exact triangle

$$\mathbb{Z}(r) \xrightarrow{p^n} \mathbb{Z}(r) \to v_n(r)[-r] \to \mathbb{Z}(r)[1].$$

Geisser and Levine [6, Theorem 8.5] show that the higher cycle complex of Bloch (on  $X_{et}$ ) satisfies this last axiom, and so we have the following result.

**Corollary 2.** Let  $\mathbb{Z}(r)$  be the higher cycle complex of Bloch on  $X_{et}$ . Then there is a canonical isomorphism

$$H^{i}_{\text{et}}(X, \mathbb{Z}(r) \xrightarrow{p^{n}} \mathbb{Z}(r)) \cong \operatorname{Hom}_{D^{b}_{c}(R)}(\mathbb{1}, R\Gamma W_{n}\Omega^{\bullet}_{X}(r)[i]).$$

### Acknowledgments

We thank P. Deligne for pointing out a misstatement in the introduction to the original version.
