Two-sided restriction semigroups and their handed versions arise from a number of sources. Attracting a deal of recent interest, they appear under a plethora of names in the literature. The class of left restriction semigroups essentially provides an axiomatisation of semigroups of partial mappings. It is known that this class admits proper covers, and that proper left restriction semigroups can be described by monoids acting on the left of semilattices. Any proper left restriction semigroup embeds into a semidirect product of a semilattice by a monoid, and moreover, this result is known in the wider context of left restriction categories. The dual results hold for right restriction semigroups.

What can we say about two-sided restriction semigroups, hereafter referred to simply as restriction semigroups? Certainly, proper covers are known to exist. Here we consider whether proper restriction semigroups can be described in a natural way by monoids acting on both sides of a semilattice.

It transpires that to obtain the full class of proper restriction semigroups, we must use partial actions of monoids, thus recovering results of Petrich and Reilly and of Lawson for inverse semigroups and ample semigroups, respectively. We also describe the class of proper restriction semigroups such that the partial actions can be mutually extendable to actions. Proper inverse and free restriction semigroups (which are proper) have this form, but we give examples of proper restriction semigroups which do not.

\textbf{0. Introduction}

Two-sided restriction semigroups and their one-sided versions arise from many sources and have equally many names. The reader can consult [12] or the unpublished notes [11] for history and further details. They first appear in the work of the Russian school in the 1960s and 1970s, useful references to this being those of Schein [23,24]. More recently they have appeared in the work of Jackson and Stokes [14] and in that of Cockett, Lack and Manes [3,19,2]. The latter authors are concerned with developing a framework to handle the notion of partiality of functions, their motivation arising from questions of theoretical computer science. From the ‘York’ perspective, two-sided (left) restriction semigroups are the varieties generated by the quasi-variety of two-sided (left) ample semigroups [10,8]. They were for some time referred to as ‘weakly (left) E-ample semigroups’. Two-sided restriction semigroups are also a special class of the ‘P-restriction semigroups’, arising from reducts of regular *-semigroups, recently introduced by Jones [15]. We refer the reader to [11] for further details and references.

Two-sided restriction semigroups form a variety of semigroups augmented with two unary operations $a \mapsto a^\downarrow$ and $a \mapsto a^\uparrow$. Since they form the focus of this article, we hereafter suppress the prefix ‘two-sided’. Every inverse semigroup is

restriction with \( a^+ = aa^{-1} \) and \( a^* = a^{-1}a \), so, as restriction semigroups form a variety, every subsemigroup of an inverse semigroup that is closed under \(^+\) and \( * \) is restriction. But certainly, not every restriction semigroup is obtained in this way. It is easy to see that any monoid \( M \) is restriction, where we declare \( a^+ = 1 = a^* \), for every \( a \in M \); such restriction semigroups are called reduced, so that a reduced inverse semigroup is simply a group. We view restriction semigroups as being natural extensions of inverse semigroups and, indeed, they have many analogous properties. This paper studies the notion of ‘proper’ for a restriction semigroup. There are some remarkable similarities to the inverse case — and some curious differences. We outline the picture in this Introduction; further details of undefined terms will be given in Section 1.

The relations additional to associativity that define restriction semigroups are:

\[
x^+x = x, \quad x^+y^+ = y^+x^+, \quad (x^+y)^+ = x^+y^+, \quad xy^+ = (xy)^+x,
\]

their duals:

\[
x^*x = x, \quad x^*y^* = y^*x^*, \quad (x^*y)^* = x^*y^*, \quad x^*y = y(xy)^*,
\]

and the connecting relations:

\[(x^+)^* = x^+ \quad \text{and} \quad (x^*)^+ = x^*.
\]

A semigroup with a unary operation of \( ^+ \) (\( ^* \)) satisfying the first (second) set of identities is called left (right) restriction. For any left restriction semigroup \( S \), we put

\[
E = \{ x^+ : x \in S \},
\]

so that if \( S \) is restriction, then by the last set of identities, we also have that \( E = \{ x^* : x \in S \} \). It is easy to see that \( E \) is a semilattice under the semigroup multiplication, the distinguished semilattice of \( S \). We remark that a restriction semigroup is proper if and only if it is proper as both a left and as a right restriction semigroup.

A classical result of McAlister [17] tells us that for any inverse semigroup \( S \), there is a proper inverse semigroup \( \hat{S} \) (a ‘proper cover’ of \( S \)) and an idempotent separating onto morphism \( \theta : \hat{S} \rightarrow S \) (a ‘covering morphism’). Correspondingly, from [8, Lemma 6.6] and [1, Theorem 6.4], every (left) restriction semigroup has a proper cover \( S \), where here \( S \) is a proper (left) restriction semigroup and now we only insist that \( \theta \) separate the idempotents of \( E \).

Of course, the power of the McAlister theory is that [17] was followed by [18], in which a structure theorem is given for proper inverse semigroups. Namely, an inverse semigroup is proper if and only if it is isomorphic to a \( P \)-semigroup \( P(G, \chi, \psi) \), where \( G \) is a group acting on a partially ordered set \( \chi \) containing a semilattice \( \psi \) as a sub-partially ordered set, subject to certain conditions. Subsequently, O’Carroll showed that an inverse semigroup is proper if and only if it can be embedded in the semidirect product of a group by a semilattice [21]. Notice that if \( S \) is proper inverse, then \( S \) is isomorphic to some \( P(S/\sigma, \chi, E(S)) \), where \( E(S) \) is the set of idempotents of \( S \) and \( \sigma \) is the least congruence identifying all the idempotents of \( E(S) \).

Correspondingly, in [1, Theorem 7.2] (which is a mild generalisation of [9, Theorem 3.6]), it is shown that a left restriction semigroup \( S \) is proper if and only if it is isomorphic to a ‘strong M-semigroup’ \( M(T, \chi, \psi) \), where \( T \) is a monoid (regarded as a reduced left restriction semigroup) acting by endomorphisms on a semilattice \( \chi \) with subsemilattice \( \psi \), again subject to certain conditions. The interested reader should note that although we can take \( \chi \) to be a semilattice, we have lost the condition ‘\( G\chi = \psi \)’ which appears in McAlister’s result. Further, if \( S \) is left restriction, then in the strong M-semigroup isomorphic to \( S \), we can take \( T = S/\sigma_{\delta} \) and \( \psi = E \), where here \( \sigma_{\delta} \) is the least congruence identifying all the idempotents of \( E \). An analogue of the O’Carroll result is also shown in [1.9] and in the wider context of left restriction categories by Cockett and Guo in [2]; curiously, such an analogue was used in [1.9] to prove the structure theorem for proper left restriction semigroups.

To complete the picture we would, of course, like a structure theorem for proper restriction semigroups, indeed, this is the aim of the current article. But, here is one of those odd situations where one-sided conditions are easier to handle than two-sided. Although it is possible to adapt the one-sided approach to the two-sided case, by adding extra conditions on M-semigroups (see [16] for the proof for the sub-quasi-variety of ample semigroups, and [4] for restriction semigroups), the results are lopsided and rather artificial.

Since restriction semigroups and monoids form varieties, free objects exist; in particular the free restriction monoid \( FRM(X) \) exists on any non-empty set \( X \). The structure of \( FRM(X) \) has recently been determined [8], the notable point for this article being that it is obtained from a monoid acting on both sides of a semilattice subject to some compatibility conditions. Since \( FRM(X) \) is proper, we were anticipating that a truly two-sided structure theorem for proper restriction semigroups would follow. This is certainly true, but not quite in the way we expected.

In Section 2 we define a strong M-quadruple \( (T, \chi, \chi', \psi) \) where \( T \) is a monoid acting on the left (right) of a semilattice \( \chi \) (\( \chi' \)) such that \( \chi \) and \( \chi' \) both contain \( \psi \) as a subsemilattice, subject to certain constraints, including compatibility conditions for the actions. We then construct a semigroup \( M(T, \chi, \chi', \psi) \) which is proper restriction.

Unfortunately, it is not the case that every proper restriction semigroup \( S \) is isomorphic to some \( M(T, \chi, \chi', \psi) \). In Section 3 we determine those \( S \) that do have this property, calling them extra proper. Inverse semigroups and free restriction monoids are extra proper, but we can easily produce examples of proper restriction semigroups that are not. Essentially, extra proper restriction semigroups have an extra amount of left/right symmetry, which is guaranteed by the existence of an involution in the inverse case.
Let $S$ be a semigroup equipped with a unary operation $a \mapsto a^+$, then $S$ is left restriction with distinguished semilattice if and only if $E \subseteq E(S)$, $E$ is a commutative subsemigroup, for every $a \in S$ the $\mathcal{R}_E$-class of $a$ contains a unique idempotent $a^+$ in $E$, the relation $\mathcal{R}_E$ is a left congruence, and the ‘ample condition’ holds, that is, for all $a \in S$ and $e \in E$, $ae = (ae)^+$.

Let $S$ be a (left) restriction semigroup. The relation $\sigma_E$ on $S$ is the least congruence identifying all the elements of $E$. As explained in [11, Section 8], we can regard $\sigma_E$ as either a semigroup congruence or a congruence in the augmented signature.

**Definition 1.3.** A left (right) restriction semigroup is proper if $\mathcal{R}_E \cap \sigma_E = \iota$ ($\mathcal{L}_E \cap \sigma_E = \iota$). A restriction semigroup is proper if it is proper as both a left and as a right restriction semigroup.

We remark that if $S$ is a proper left restriction semigroup, then $E$ is a $\sigma_E$-class, but the converse need not be true [6, Example 3]. However, it is well known that an inverse semigroup (for which we always have $\mathcal{R}_{E(S)} = \mathcal{R}$) is proper if and only if it is $E$-unitary, that is, if and only if $E(S)$ forms a $\sigma = \sigma_{E(S)}$-class.

Our aim is to find a structure theorem for proper restriction semigroups: our tools will be actions and partial actions of monoids on partially ordered sets and semilattices.

**Definition 1.4.** Let $T$ be a monoid and let $X$ be a set. Then $T$ acts on $X$ (on the left) if there is a map $T \times X \to X$, $(t, x) \mapsto t \cdot x$, such that for all $x \in X$ and $s, t \in T$ we have

$$1 \cdot x = x \quad \text{and} \quad st \cdot x = s \cdot (t \cdot x).$$

**Definition 1.5.** Let $T$ be a monoid and let $X$ be a set. Then $T$ acts partially on $X$ (on the left) if there is a partial map $T \times X \to X$, $(t, x) \mapsto t \cdot x$, such that for all $s, t \in T$ and $x \in X$,

$$\exists 1 \cdot x \quad \text{and} \quad 1 \cdot x = x$$

and

$$\text{if } \exists t \cdot x \quad \text{and} \quad \exists s \cdot (t \cdot x) \quad \text{then } \exists st \cdot x \text{ and } s \cdot (t \cdot x) = st \cdot x,$$

where we write $\exists u \cdot y$ to indicate that $u \cdot y$ is defined.

Of course, a partial left action of $T$ on $X$ with domain of the action $T \times X$ is an action. Dually, we may define the (partial) right action of $T$ on $X$.

**Definition 1.6.** If a monoid $T$ acts on (the left of) a partially ordered set $X$ (semilattice $Y$), then the action is order preserving (by morphisms) if, for any $t \in T$ and $x, y \in X$ with $x \leq y$, $e, f \in Y$, we have that

$$t \cdot x \leq t \cdot y \quad (t \cdot (e \land f) = (t \cdot e) \land (t \cdot f)).$$
Notice that if a monoid acts by morphisms on a semilattice $Y$, then its action is order preserving, but the converse need not be true. If a group $G$ acts by order preserving maps on a partially ordered set, then, as any group action is by bijections, it acts by order automorphisms.

Suppose now that the monoid $T$ acts by morphisms on a semilattice $Y$. We denote by $Y * T$ the semidirect product of $Y$ and $T$, so that

$$Y * T = Y \times T \quad \text{and} \quad (e, s)(f, t) = (e \wedge (s \cdot f), st)$$

for all $(e, s), (f, t) \in Y * T$. It is an easy exercise to check that $Y * T$ is proper left restriction with $(e, s)^+ = (e, 1)$ and inverse if $T$ is a group. Unfortunately, semidirect products of this kind do not even yield all proper inverse semigroups, which is where the McAlister construction using $P$-semigroups comes into play. Nevertheless, the ideas underlying all attempts to describe proper semigroups are adaptations of the notion of semidirect product.

There are various approaches to constructing a 'P-theorem' for left restriction semigroups and their specialisations (see [6, 16, 9, 1]). The one we now describe is that of [1], since it is this construction that we need in detail for Theorem 3.5.

**Definition 1.7.** Let $T$ be a monoid acting by morphisms on the left of a semilattice $X$ having subsemilattice $Y$. Suppose that there exists an upper bound $e$ for $Y$ in $X$ such that the following hold:

(a) for all $t \in T$, there exists $e \in Y$ such that $e \leq t \cdot e$;
(b) for all $e, f \in Y$ and all $t \in T$,

$$e \leq t \cdot e \implies e \wedge t \cdot f \text{ lies in } Y.$$

Then the triple $(T, X, Y)$ is called a strong left $M$-triple.

We note that in [1], strong left $M$-triples were referred to for simplicity as strong $M$-triples. Given a strong left $M$-triple $(T, X, Y)$, we define

$$M = M(T, X, Y) = \{(e, s) \in Y \times T : e \leq s \cdot e\},$$

with binary operation defined by

$$(e, s)(f, t) = (e \wedge s \cdot f, st)$$

for $(e, s), (f, t) \in M$. We shall call $M(T, X, Y)$ a strong $M$-semigroup.

Dually, we may define the notion of a strong right $M$-triple $(T, X, Y)$, where $T$ acts on the right of $X$ satisfying the duals of Conditions (a) and (b), and then a semigroup $M^r = M^r(T, X, Y) = \{(s, e) \in T \times Y : e \leq s \cdot e \cdot t\}$ under the appropriate semidirect product multiplication.

**Proposition 1.8 ([1, Lemma 7.1]).** Let $(T, X, Y)$ be a strong $M$-triple. Then $M(T, X, Y)$ is a proper left restriction semigroup with

$$(e, s)^+ = (e, 1), \quad E = \{(e, 1) : e \in Y\} \cong Y \quad \text{and} \quad M(T, X, Y) / \sigma_e \cong T.$$

A left restriction semigroup $S$ with $E = E(S)$ is weakly left ample; if, in addition, $\bar{R}_{E(S)} = R^*$, then $S$ is left ample. The obvious definitions then apply to give (weakly) (right) ample semigroups.

**Theorem 1.9 ([9, 1]).** A semigroup is proper left restriction (weakly left ample, left ample) if and only if it is isomorphic to a strong $M$-semigroup $M(T, X, Y)$ for some strong left $M$-triple $(T, X, Y)$ (where $T$ is unipotent, right cancellative).

We note that the above result in the left ample case can easily be deduced from the given references. The original description of proper left ample semigroups appears in [6] and was reworked in [16].

### 2. Double actions and semigroups $M(T, X, X', Y)$

As explained in the Introduction, our aim is to describe proper restriction semigroups in a way that is genuinely two-sided. Inspiration arose from the definition of a double action [8], used to determine the structure of the free ample monoid.

**Definition 2.1.** Let $T$ be a monoid and let $Y$ be a semilattice with identity. Then $T$ acts doubly on $Y$ if $T$ acts by morphisms on the left and right of $Y$ and the compatibility conditions hold, that is, for all $t \in T$ and $e \in Y$,

$$(t \cdot e) \circ t = (1 \circ t)e \quad \text{and} \quad t \cdot (e \circ t) = e(t \cdot 1).$$

It is proved in [8, Lemma 6.2] that if a monoid $T$ acts doubly on a semilattice $Y$ with identity, then the set

$$S = \{(e, s) : e \leq s \cdot 1\} \subseteq Y * T$$

with

$$(e, s)(f, t) = (e \wedge s \cdot f, st) \quad \text{and} \quad (e, s)^+ = (e, 1)$$

is a proper restriction monoid.

Moreover, the free restriction monoid is proper and has a structure as above, suggesting that we could use the idea of a double action to produce a structure theorem for proper restriction monoids and semigroups. The natural way is to proceed as follows.
Definition 2.2. Let $\mathcal{X}$ and $\mathcal{X}'$ be semilattices and $\mathcal{Y}$ be a subsemilattice of both $\mathcal{X}$ and $\mathcal{X}'$. Let $\varepsilon, \varepsilon' \in \mathcal{X}$ such that $a \leq \varepsilon, \varepsilon'$ for all $a \in \mathcal{Y}$. Let $T$ be a monoid with identity 1, which acts by morphisms on the left of $\mathcal{X}$ via $\cdot$ and on the right of $\mathcal{X}'$ via $\circ$.

Suppose in addition that for all $t \in T$ and $e \in \mathcal{Y}$, the following hold:

(A) $e \leq t \cdot \varepsilon \Rightarrow e \circ t \in \mathcal{Y}$;
(B) $e \leq \varepsilon' \circ t \Rightarrow t \cdot e \in \mathcal{Y}$;
(C) $e \leq t \cdot \varepsilon \Rightarrow t \cdot (e \circ t) = e$;
(D) $e \leq \varepsilon' \circ t \Rightarrow (t \cdot e) \circ t = e$;
(E) for all $t \in T$, there exists $e \in \mathcal{Y}$ such that $e \leq t \cdot \varepsilon$.

We then say that $(T, \mathcal{X}, \mathcal{X}', \mathcal{Y})$ is a strong $M$-quadruple.

The above may look a little lopsided, but, in view of the following, it is not.

Lemma 2.3. Let $(T, \mathcal{X}, \mathcal{X}', \mathcal{Y})$ be a strong $M$-quadruple. Then

(F) for all $t \in T$, there exists $b \in \mathcal{Y}$ such that $b \leq \varepsilon' \circ t$ holds.

Proof. Taking $t \in T$, by (E), there exists $a \in \mathcal{Y}$ such that $a \leq t \cdot \varepsilon$. By (A), $a \circ t \in \mathcal{Y}$ and clearly $a \circ t \leq \varepsilon' \circ t$. □

Proposition 2.4. Let $(T, \mathcal{X}, \mathcal{X}', \mathcal{Y})$ be a strong $M$-quadruple. Then $(T, \mathcal{X}, \mathcal{Y})$ is a strong left $M$-triple. Dually, $(T, \mathcal{X}', \mathcal{Y})$ is a strong right $M$-triple.

Proof. It only remains to show that if $e, f \in \mathcal{Y}$ and $t \in T$ with $e \leq t \cdot \varepsilon$, then $e \land t \cdot f \in \mathcal{Y}$. We have $e \circ t \in \mathcal{Y}$ by Condition (A). Then

$$(e \circ t) \land f \leq e \circ t \leq \varepsilon' \circ t.$$ 

Using Conditions (C) and (B), we now have

$$e \land t \cdot f = t \cdot ((e \circ t) \land f) = t \cdot ((e \circ t) \land f) \in \mathcal{Y}. \quad \square$$

Let $(T, \mathcal{X}, \mathcal{X}', \mathcal{Y})$ be a strong $M$-quadruple. We define

$${\mathcal{M}} = {\mathcal{M}}(T, \mathcal{X}, \mathcal{X}', \mathcal{Y}) = {\mathcal{M}}(T, \mathcal{X}, \mathcal{Y}) \quad \text{and} \quad {\mathcal{M}}' = {\mathcal{M}}'(T, \mathcal{X}, \mathcal{X}', \mathcal{Y}) = {\mathcal{M}}'(T, \mathcal{X}', \mathcal{Y}).$$

Proposition 2.5. Let $(T, \mathcal{X}, \mathcal{X}', \mathcal{Y})$ be a strong $M$-quadruple as above. Then

$$\theta : \mathcal{M} \rightarrow \mathcal{M}'$$

is a semigroup isomorphism.

Proof. First note that if $(e, s) \in \mathcal{M}$ then by Condition (A), $e \circ s \in \mathcal{Y}$ and $e \circ s \leq \varepsilon' \circ s$, so $(s, e \circ s) \in \mathcal{M}'$.

If $(e, s), (f, t) \in \mathcal{M}$ and $(e, s) \theta = (f, t) \theta$, then clearly $s = t$ and $e \circ t = f \circ t$. As $e, f \leq t \cdot \varepsilon$, we have by Condition (C) that $e = t \cdot (e \circ t) = t \cdot (f \circ t) = f$.

Thus $\theta$ is one–one.

Choosing $(u, g) \in \mathcal{M}'$, we have that $g \leq \varepsilon' \circ u$, so that $u \cdot g \in \mathcal{Y}$ and as $u \cdot g \leq u \cdot \varepsilon$, we have that $(u \cdot g, u) \in \mathcal{M}$. Now using Condition (D),

$$(u \cdot g, u) \theta = (u, (u \cdot g) \circ u) = (u, g),$$

so that $\theta$ is onto, and hence a bijection.

To see that $\theta$ is an isomorphism, let $(e, s), (f, t) \in \mathcal{M}$. Then

$$(e, s) \theta (f, t) \theta = (s, e \circ s)(t, f \circ t)$$
$$= (st, ((e \circ s) \circ t) \land f \circ t)$$
$$= (st, (e \circ s \land f) \circ t).$$

Now, $(e \circ s) \land f \leq e \circ s \leq \varepsilon' \circ s$, so

$$(e \circ s) \land f = (s \cdot ((e \circ s) \land f)) \circ s$$
$$= ((s \cdot (e \circ s)) \land s \cdot f) \circ s$$
$$= (s \land s \cdot f) \circ s.$$
We can now give the main result of this section.

**Theorem 2.6.** Let \((T, X, X', Y)\) be a strong \(M\)-quadruple. Then \(\mathcal{M} = \mathcal{M}(T, X, X', Y)\) is a proper restriction semigroup such that

\[
(e, t)^+ = (e, 1), \quad (e, t)^* = (e \circ t, 1), \quad E = \{(e, 1) : e \in Y\} \quad \text{and} \quad \mathcal{M}/\sigma_E \cong T.
\]

**Proof.** From Proposition 1.8, we know that \(\mathcal{M}\) is proper left restriction with \((e, t)^+ = (e, 1), E = \{(e, 1) : e \in Y\}\) and \(\mathcal{M}/\sigma_E \cong T\). Dually, \(\mathcal{M}'\) is a proper right restriction with \((t, e)^+ = (1, e)\) and distinguished semilattice \(E'\) where \(E' = \{(1, e) : e \in Y\}\). Clearly \(E \theta = E'\), where \(\theta\) is the isomorphism from \(\mathcal{M}\) to \(\mathcal{M}'\) given in Proposition 2.5, so that \(\mathcal{M}\) is proper restriction with

\[
(e, s)^* = \left((e, s)\theta^*-1\right) = (s, e \circ s)^{-1} = (1, e \circ s)^{-1} = (e \circ s, 1). \quad \Box
\]

In view of Theorem 1.9 we may easily adapt Theorem 2.6 to special cases.

**Corollary 2.7.** Let \((T, X, X', Y)\) be a strong \(M\)-quadruple and let \(\mathcal{M} = \mathcal{M}(T, X, X', Y)\). If \(T\) is unipotent, then the proper restriction semigroup \(\mathcal{M}\) is weakly ample, and if \(T\) is left (right) cancellative, then \(\mathcal{M}\) is right (left) ample.

**Corollary 2.8.** Let \((G, X, X', Y)\) be a strong \(M\)-quadruple and let \(\mathcal{M} = \mathcal{M}(G, X, X', Y)\). If \(G\) is a group, then \(\mathcal{M}\) is proper inverse, such that

\[
(a, t)' = (t^{-1} \cdot a, t^{-1})
\]

for any \((a, t) \in \mathcal{M}\).

**Proof.** As a group is a cancellative monoid, \(\mathcal{M}\) is proper ample by Corollary 2.7.

For any \((a, t) \in \mathcal{M}\) we notice that, as \(a \leq t \cdot e\), we have that \(a \circ t \in Y\) and \(t \cdot (a \circ t) = a\). Using the left action of \(t^{-1}\) we obtain \(t^{-1} \cdot a = a \ circ t \circ e\). Since \(t^{-1} \cdot a \leq t^{-1} \cdot e\), we have \((t^{-1} \cdot a, t^{-1}) \in \mathcal{M}\). It is theneasy to check that \((a, t)\) and \((t^{-1} \cdot a, t^{-1})\) are mutually inverse, and so the idempotents of \(\mathcal{M}\) form a semilattice, \(\mathcal{M}\) is inverse. \(\Box\)

3. Extra proper restriction semigroups

We would like to be able to say that every proper restriction semigroup is isomorphic to \(\mathcal{M}(T, X, X', Y)\) for some strong \(M\)-quadruple \((T, X, X', Y)\). Unfortunately, this is not the case.

**Lemma 3.1.** Let the proper restriction semigroup \(S\) be isomorphic to \(\mathcal{M}(T, X, X', Y)\) for some strong \(M\)-quadruple \((T, X, X', Y)\). Then

\[
E \cong Y \quad \text{and} \quad S/\sigma_E \cong T.
\]

**Proof.** Since the isomorphism preserves \(\circ\) and \(+\),

\[
E \cong \{(e, 1) : e \in Y\} = Y' \cong Y
\]

and so

\[
S/\sigma_E \cong \mathcal{M}/\sigma_Y \cong T. \quad \Box
\]

**Proposition 3.2.** Let \(S\) be a finite proper ample semigroup. Suppose that \(S\) is isomorphic to \(\mathcal{M} = \mathcal{M}(T, X, X', Y)\) for some strong \(M\)-quadruple \((T, X, X', Y)\). Then \(S\) is inverse.

**Proof.** From [6, Lemma 1.3] (adjusted to the semigroup case) we have that \(S/\sigma_E\) is cancellative. By Lemma 3.1, \(T\) is cancellative and hence a group by finiteness. If we let \((e, t) \in \mathcal{M}\), then \(e \leq t \cdot e\), so \(e \circ t \in Y\) and \(e \circ (e \circ t) = e \circ t\). Hence \(e = t \cdot (t^{-1} \cdot e) = t \cdot (e \circ t)\) and so \(t^{-1} \cdot e = e \circ t\). As \(t^{-1} \cdot e \leq t^{-1} \cdot e\), we see that \((t^{-1} \cdot e, t^{-1}) \in \mathcal{M}\) and

\[
(e, t)(t^{-1} \cdot e, t^{-1})(e, t) = (e, 1)(e, t) = (e, t),
\]
giving that \(\mathcal{M}\) is regular. Since \(E(\mathcal{M})\) is a semilattice, \(\mathcal{M}\) is inverse. \(\Box\)

We remark that finite proper ample semigroups that are not inverse certainly exist. From [7, Theorem 3.2 and Corollary 3.3], every finite ample semigroup has a finite proper ample cover, so that if all finite proper restriction semigroups were inverse, all finite ample semigroups would also be inverse. Let \(I_2\) be the symmetric inverse semigroup on \([1, 2]\) and let \(\alpha \in I_2\) be defined by dom \(\alpha = \{1\}\), \(1\alpha = 2\). Then \(S = [\alpha, \alpha^+, \alpha^*, \emptyset]\) is a subsemigroup of \(I_2\) closed under \(+\) and \(*\), which is ample but not inverse.

In order to isolate those proper restriction semigroups that are isomorphic to some \(\mathcal{M}(T, X, X', Y)\), we introduce the following notion.

Let \(S\) be a restriction semigroup. Then \(S\) satisfies Condition \((EP)\) if it satisfies \((EP)^\prime\) and its dual \((EP)^\dagger\).

\((EP)^\prime\): for all \(s, t, u \in S\), if \(s \sigma_E tu\) then there exists \(v \in S\) with \(t^+ s = t u\) and \(u \sigma_E v\).

**Lemma 3.3.** Let \(S\) be a restriction semigroup satisfying Condition \((EP)\) such that \(E\) is a \(\sigma_E\)-class. Then \(S\) is proper.

**Proof.** Let \(a, b \in S\) and suppose that \(a \circ (\hat{R}_E \cap \sigma_E) b\). Then \(a \sigma_E b^+ a^*\), so with \(s = a, t = b, u = b^*\) in \((EP)^\prime\) we have that \(b^+ a = b v\) for some \(v \in S\) with \(b^+ \sigma_E v\), giving \(v \in E\). But \(b^+ = a^+\) and so \(a = b v = (bv)^+ b = a^+ b = b\). Dually, \(\hat{L}_E \cap \sigma_E\) is trivial. \(\Box\)
**Definition 3.4.** Let $S$ be a proper restriction semigroup. Then $S$ is **extra proper** if it satisfies Condition (EP).

**Theorem 3.5.** Let $S$ be a proper restriction semigroup. Then $S$ is isomorphic to some $\mathcal{M}(T, \mathcal{X}, \mathcal{X}', \mathcal{Y})$ if and only if $S$ is extra proper.

**Proof.** Let $\mathcal{M} = \mathcal{M}(T, \mathcal{X}, \mathcal{X}', \mathcal{Y})$ for some strong M-quadruple $(T, \mathcal{X}, \mathcal{X}', \mathcal{Y})$. We show that $\mathcal{M}$ is extra proper.

Let $\alpha, \beta, \gamma \in \mathcal{M}$ be such that

$$\alpha \sigma_{\mathcal{E}} \beta \gamma.$$

Then we must have that $\beta = (e, s)$, $\gamma = (f, t)$ and $\alpha = (g, st)$ for some $e, f, g \in \mathcal{Y}$ and $s, t \in T$.

We have that

$$e \wedge g \leq e \leq s \cdot e$$

so that by $(A), (e \wedge g) \circ s \in \mathcal{Y}$ and so $(e \wedge g) \circ s \leq e'$. Since the action of $t$ is order preserving, this gives us that $(e \wedge g) \circ st \leq e' \circ t$. Also, as

$$e \wedge g \leq g \leq st \cdot e$$

we have that $(e \wedge g) \circ st \in \mathcal{Y}$. Since also $(e \wedge g) \circ st \leq e' \circ t$, $(B)$ gives that $t \cdot ((e \wedge g) \circ st) \in \mathcal{Y}$. Now $(e \wedge g) \circ st \leq e$ and so $t \cdot ((e \wedge g) \circ st) \leq t \cdot e$, yielding that

$$v = (t \cdot ((e \wedge g) \circ st), t) \in \mathcal{M}.$$

Clearly, $v \sigma_{\mathcal{E}} \gamma$ and

$$\beta v = (e, s) (t \cdot ((e \wedge g) \circ st), t) = (e \wedge (s \cdot (t \cdot ((e \wedge g) \circ st))), st)$$

$$= (e \wedge (s \cdot (t \cdot ((e \wedge g) \circ st))), st) = (e \wedge (e \wedge g), st) = (e, 1)(g, st) = \beta'^{+} \alpha.$$

We have shown that $\mathcal{M}$ satisfies $(EP)$. From Lemma 3.1, $\mathcal{M} \cong \mathcal{M}' = \mathcal{M}'(T, \mathcal{X}', \mathcal{Y})$ and by duality, we must have that $\mathcal{M}'$ satisfies $(EP)^{\prime}$. As the isomorphism between $\mathcal{M}$ and $\mathcal{M}'$ preserves the distinguished semilattices, we must have that $\mathcal{M}$ satisfies $(EP)^{\prime}$ also.

To prove the converse, we use the construction of the strong M-triple associated with a proper restriction semigroup $S$ given in [1, Theorem 7.2]. Before doing so, we make the following remark, that will help us over an awkward point in our argument.

Suppose we have disjoint semilattices $\mathcal{X}$ and $\mathcal{X}'$ containing subsemilattices $\mathcal{Y}$ and $\mathcal{Y}'$ respectively, such that there is an isomorphism $\theta : \mathcal{Y} \to \mathcal{Y}'$. Suppose that there are upper bounds $e \in \mathcal{X}$ and $e' \in \mathcal{X}'$ of $\mathcal{Y}$ and $\mathcal{Y}'$, respectively. Let $T$ be a monoid with identity 1, which acts by morphisms on the left of $\mathcal{X}$ via $\cdot$ and on the right of $\mathcal{X}'$ via $\circ$.

Suppose in addition that for all $t \in T$ and $e \in \mathcal{Y}$, the following hold:

(A)' $e \leq t \cdot e \Rightarrow e \theta \circ t \in \mathcal{Y}'$

(B)' $e \theta \leq e' \circ t \Rightarrow t \cdot e \in \mathcal{Y}$

(C)' $e \leq t \cdot e \Rightarrow t \cdot (e \theta \circ t) \theta^{-1} = e$

(D)' $e \theta \leq e' \circ t \Rightarrow (t \cdot e \theta) \circ t = e \theta$

(E) for all $t \in T$, there exists $e \in \mathcal{Y}$ such that $e \leq t \cdot e$.

Then, by suitable relabelling, it is possible to construct a strong M-quadruple $(T, \mathcal{X}, \mathcal{X}'', \mathcal{Y})$ where $\mathcal{X}'' = (\mathcal{X}' \setminus \mathcal{Y}) \cup \mathcal{Y}$.

Suppose now that $\mathcal{S}$ is extra proper. From [1, Theorem 7.2], $S$ is isomorphic to $\mathcal{M} = \mathcal{M}(T, B^{T}, \mathcal{Y})$ for some strong M-triple $(T, B^{T}, \mathcal{Y})$ constructed as below.

First, $T = S/\sigma_{\mathcal{E}}$. We then let $B$ be the semilattice of ideals of $E$ with a zero adjoined. Notice that if $I, J$ are ideals of $B$, then $I \wedge J = I \cap J$ and $I \leq J$ if and only if $I \subseteq J$. We have that $B^{T}$ is the semilattice of all maps from $T$ into $B$, with operation defined by $\alpha(fg) = (\alpha f) \circ (\alpha g)$ for all $\alpha \in T$ and for all $f, g \in B^{T}$. Moreover, $T$ acts on the left of $B^{T}$ via $\alpha (\beta \cdot f) = (\alpha \beta) f$, for all $\alpha, \beta \in T$ and $f \in B^{T}$.

For any $e \in E$, the map $f_{e} \in B^{T}$ is defined by

$$(\sigma_{\mathcal{E}} f_{e}) = \{(ne)^{+} : n \sigma_{\mathcal{E}} t\}$$

and then

$$\mathcal{Y} = \{f_{e} : e \in E\}$$

is a subsemilattice of $B^{T}$ isomorphic to $E$ via $e \mapsto f_{e}$. Defining $e \in B^{T}$ by

$$(\sigma_{\mathcal{E}} e) = \{m^{+} : m \sigma_{\mathcal{E}} t\}$$

we have that $e$ is an upper bound for $\mathcal{Y}$ in $B^{T}$. Moreover, $(T, B^{T}, \mathcal{Y})$ is a strong M-triple and $S$ is isomorphic to $\mathcal{M}(T, B^{T}, \mathcal{Y})$ via a $(2, 1)$-isomorphism $\psi$, where $s \psi = (f_{e}, \sigma_{\mathcal{E}} e)$.

We show that the strong M-triple $(T, B^{T}, \mathcal{Y})$ can be extended to a strong M-quadruple $(T, B^{T}, \mathcal{X}', \mathcal{Y})$, for some partially ordered set $\mathcal{X}'$. 
By the dual of [1, Theorem 7.2], we can construct a strong right M-triple \((T, \overline{T}B, \gamma')\), where \(\overline{T}B\) is the semilattice of functions from \(T\) to \(B\) written on the left of their arguments, and \(T\) acts on \(B\) on the right via \((f \circ \alpha)(\beta) = f(\alpha \beta)\) for all \(f \in \overline{T}B\) and \(\alpha, \beta \in T\). For any \(e \in E\) we define \(g_e \in \overline{B}\) by
\[
g_e(t\sigma_e) = \{(e^\ast)^s : m \sigma_e \in t\}
\]
and put \(\gamma' = \{g_e : e \in E\}.\) Then \(\gamma'\) is a subsemilattice of \(\overline{T}B\) isomorphic to \(E\) via \(e \mapsto g_e.\) It follows that \(\theta : \gamma' \to \gamma'\) given by \(f_e \theta = g_e\) is an isomorphism. Finally, \(\epsilon' \in T\) defined by
\[
\epsilon'((t\sigma) = \{m^\ast : m \sigma_e \in t\}
\]
is an upper bound for \(\gamma'\) in \(\overline{T}B\) which enables the conditions for \((T, \overline{T}B, \gamma')\) to be a strong right M-triple to be satisfied.

We need to show that Conditions \(\{A\}'\)–\(\{D\}'\) are satisfied. We show that \(\{A\}'\) and \(\{C\}'\) hold; \(\{B\}'\) and \(\{D\}'\) then follow by duality.

We first show that for any \(s \in S, g_{s^+} \circ s \sigma_{E'} = g_s^\ast.\)

Let \(r \sigma = T.\) Then
\[
g_{s^+}((r \sigma) = \{(s^h)^s : h \sigma_e \in r\}
\]
and it follows that
\[
g_{s^+}((r \sigma) = (g_{s^+} \circ s \sigma_{E'})(r \sigma).
\]

Since \(r \sigma_{E'}\) was any element of \(T, g_{s^+} = g_{s^+} \circ s \sigma_{E'}\) as required. By duality, \(s \sigma_{E'} \cdot f_{s^+} = f_{s^+}\)

Let \(f_e \in \gamma', t \sigma_e \in T\) and suppose that \(f_e \leq t \sigma_e \cdot e.\) From the proof of [1, Theorem 7.2], there is an \(s \in S\) such that \(s^+ = e\) and \(s \sigma_e \cdot t.\) By the above, we have that
\[
f_e \theta \circ t \sigma_e = g_e \circ t \sigma_e = g_{s^+} \circ s \sigma_{E'} = g_{s^+} \in \gamma'
\]
so that Condition \(\{A\}'\) holds. Further,
\[
s \sigma_{E'} \cdot (f_{s^+} \circ s \sigma_{E'}) \cdot \theta^{-1} = s \sigma_{E'} \cdot g_{s^+} \cdot \theta^{-1} = s \sigma_{E'} \cdot f_{s^+} = f_{s^+}
\]
so that Condition \(\{C\}'\) holds.

From the remarks at the beginning of this direction of the proof, relabelling will produce a strong M-triple \((T, B^T, \overline{T}B, \gamma')\) as required. It remains to show that \(\theta\) preserves \(\ast.\) If \(s \in S,\) then (bearing in mind that we have identified \(\gamma\) and \(\gamma')\), we have
\[
(s^h)^s = (f_{s^+} \cdot s \sigma_{E'})^s = (f_{s^+} \circ s \sigma_{E'}, 1) = (f_{s^+}, 1) = s^h \theta
\]
so that \(\theta\) is an isomorphism in the signature \((2, 1, 1),\) as required.

**Example 3.6.** Every inverse semigroup has \((EP)\). For, if \(s, t, u\) are elements of an inverse semigroup \(S\) with \(s \sigma tu,\) then \(t^s = s^t u\) and \(t^s = s^t u\).

**Example 3.7.** Every reduced restriction semigroup has \((EP)\). For, if \(s, t, u\) are elements of a reduced restriction semigroup \(S\) with \(s \sigma tu,\) then \(s = tu\) and \(t^s = s^t u.\)

Less trivially, free restriction monoids have \((EP)\).

**Example 3.8.** Let \(\mathcal{F}RM(X)\) be the free restriction monoid on a non-empty set \(X.\) We use the characterisation of \(\mathcal{F}RM(X)\) as a submonoid of the free inverse monoid \(\mathcal{FI}M(X)\) on \(X\), given in [8].

Let \(\mathcal{F}G(X)\) be the free group on \(X,\) and regard elements of \(\mathcal{F}G(X)\) as reduced words over \(X.\) Let \(\gamma = \{A \subseteq \mathcal{F}G(X) : 1 \leq |A| < \infty, A\) is prefix closed\}.\)

Then
\[
\mathcal{FI}M(X) = \{(A, w) : A \subseteq \gamma, w \in A\}
\]
with
\[
(A, w)(B, v) = (A \cup wB, wv) \quad \text{and} \quad (A, w)^{-1} = (w^{-1}A, w^{-1}).
\]

From [8], \(\mathcal{F}RM(X)\) is the submonoid of \(\mathcal{FI}M(X)\) given by
\[
\mathcal{F}RM(X) = \{(A, w) \in \mathcal{FI}M(X) : w \in X^\ast\}
and for any \((A, w), (B, v) \in \mathcal{FRM}(X)\), we have that

\[(A, w)^+ = (A, 1) \text{ and } (A, w) \sigma_E (B, v) \text{ if and only if } w = v.\]

Suppose that \((A, w), (B, v), (C, u) \in \mathcal{FRM}(X)\) with\((A, w) \sigma (B, v)(C, u).

Then \(w = vu\) and

\[(B, v)(A, w) = (B, v)(B, v)^{-1}(A, w) = (B, v)(v^{-1}B, v^{-1})(A, w) = (B, v)(v^{-1}B \cup v^{-1}A, v^{-1}w) = (B, v)(v^{-1}B \cup v^{-1}A, u)\]

and as \((v^{-1}B \cup v^{-1}A, u) \in \mathcal{FRM}(X), \text{Condition (EP)}^f \text{ holds. Dually, (EP)}^f \text{ holds.}\]

Finally in this section we give an example of an infinite proper ample semigroup without (EP), also showing that a proper ample semigroup can be a \((2, 1, 1)\)-subalgebra of a proper inverse semigroup, yet not itself be extra proper.

**Example 3.9.** Let \(X\) be a set with at least two elements, and let \(X_i = \{x_i : x \in X\}\) for \(i \in \{0, 1\}\) be sets in one–one correspondence with \(X\). Let \(S\) be a strong semilattice \(Y = \{1, 0\}\) of cancellative monoids \(S_1 = X_1^+\) and \(S_2 = \mathcal{F}^\gamma(X_0)\), with connecting morphism \(\phi_{1,0}\) given by \(x_i\phi_{1,0} = x_0\).

It follows from [5, Theorem 1] that \(S\) is ample, with \(\mathcal{R}^* = \mathcal{L}^* = \mathcal{H}^*\)-classes \(S_1\) and \(S_0\). As the connecting homomorphism is one–one, it is easy to see that \(S\) is proper.

Let \(x, y\) be distinct elements of \(X\). Then

\[e_0x_1 = x_0 = y_0(y_0^{-1}x_0) = e_0(y_1y_0^{-1}x_0)\]

so that \(x_1 \tau_x y_1(y_0^{-1}x_0)\). If \(y_1x_1 = y_1w\) for some \(w \in S\) we would have that \(x_1 = y_1w\), which is impossible.

### 4. Partial actions and semigroups \(\mathcal{M}(T, \gamma)\)

In this section we use partial actions to define the notion of a strong \(M\)-pair \((T, \gamma)\), where \(T\) is a monoid acting partially on both sides of a semilattice \(\gamma\), based on strong \(M\)-triples and quadruples. From a strong \(M\)-pair \((T, \gamma)\) we can define a semigroup \(\mathcal{M}(T, \gamma)\) which is proper restriction. In Section 5 we show that, conversely, every proper restriction semigroup is isomorphic to some \(\mathcal{M}(T, \gamma)\). Our construction is analogous to that of Petrich and Reilly in the inverse case [22] and that of Lawson in the ample case [16]. However, our proofs are new and direct.

Let \(T\) be a monoid, acting partially on the left and right of a semilattice \(\gamma\), via \(\cdot\) and \(\circ\) respectively. Suppose that both actions preserve the partial order and the domains of each \(t \in T\) are order ideals, that is, for each \(t \in T\) and \(e, f \in \gamma\) with \(e \leq f\), if \(\exists t \cdot f (\exists f \circ t)\), then \(\exists t \cdot e (\exists e \circ t)\) and \(t \cdot e \leq t \cdot f (e \circ t \leq f \circ t)\). Suppose in addition that for \(e \in \gamma\) and \(t \in T\), the following hold:

(A) if \(\exists e \circ t\), then \(\exists t \cdot (e \circ t)\) and \(t \cdot (e \circ t) = e\);
(B) if \(\exists t \cdot e\), then \(\exists (t \cdot e) \circ t\) and \((t \cdot e) \circ t = e\);
(C) for all \(t \in T\), there exists \(e \in \gamma\) such that \(\exists e \circ t\).

We then say that the pair \((T, \gamma)\) is a strong \(M\)-pair. It is clear from Conditions (A) and (C) that a strong \(M\)-pair also satisfies the dual of Condition (C). Notice that the partial actions of an element \(t\) of \(T\) on the left and right of \(\gamma\) are mutually inverse on their respective domains.

For a strong \(M\)-pair \((T, \gamma)\) we define

\[\mathcal{M} = \mathcal{M}(T, \gamma) = \{(e, s) \in \gamma \times T : \exists e \circ s\}\]

with binary operation given by

\[(e, s)(f, t) = (s \cdot ((e \circ s) \land f), st)\]

Dually, we can define \(\mathcal{M}' = \mathcal{M}'(T, \gamma)\).

To proceed to show that \(\mathcal{M}\) is a semigroup, we require a technical result.

**Proposition 4.1.** Let \((T, \gamma)\) be a strong \(M\)-pair. Then:

1. if \(\exists e \circ a\) and \(\exists f \circ a\), then \(\exists (e \land f) \circ a\) and \(e \circ a \land f \circ a = (e \land f) \circ a\);
2. if \(\exists a \cdot e\) and \(\exists a \cdot f\), then \(\exists a \cdot (e \land f)\) and \(a \cdot e \land a \cdot f = a \cdot (e \land f)\).
Suppose $T$ to see that the binary operation in $\mathcal{M} = \mathcal{M}(T, \mathcal{Y})$ is a proper restriction semigroup with

$$(e \land f) \circ a \leq e \circ a \land f \circ a.$$

Conversely, as $\exists e \circ a$, Condition (A) gives that $\exists (e \circ a) = e$. As $e \circ a \land f \circ a \leq e \circ a$ we must have $\exists (e \circ a \land f \circ a)$ since the domain of $\circ$ is an order ideal. Since $\circ$ is order preserving,

$$a \cdot (e \circ a \land f \circ a) \leq a \cdot (e \circ a) = e.$$

Similarly, $a \cdot (e \circ a \land f \circ a) \leq f$ and so $a \cdot (e \circ a \land f \circ a) \leq e \land f$.

From Condition (B), $\exists [a \cdot (e \circ a \land f \circ a)] \circ a$ and

$$e \circ a \land f \circ a = [a \cdot (e \circ a \land f \circ a)] \circ a \leq (e \land f) \circ a.$$

Hence $e \circ a \land f \circ a = (e \land f) \circ a$ and so (1) holds. The proof of (2) is dual. \hfill \Box

**Theorem 4.2.** Let $(T, \mathcal{Y})$ be a strong M-pair. Then $\mathcal{M} = \mathcal{M}(T, \mathcal{Y})$ is a proper restriction semigroup with

$$(e, a)^+ = (e, 1), \quad (e, a)^* = (e \circ a, 1), \quad E = \{ (e, 1) : e \in \mathcal{Y} \} \cong \mathcal{Y} \quad \text{and} \quad \mathcal{M}/\sigma_T \cong T.$$

If $T$ is unipotent, $(right, left)$ cancellative, then $\mathcal{M}$ is weakly ample, $(left, right)$ ample, respectively.

**Proof.** To see that the binary operation in $\mathcal{M}$ is well-defined, let $(e, a), (f, b) \in \mathcal{M}$. We wish to show $(a \cdot ((e \circ a) \land f), ab) \in M$.

By Condition (A), $\exists e \circ a$ since $\exists e \circ a$. As $e \circ a \land f \leq e \circ a$, certainly $\exists e \circ a \land f$.

We wish to show that $\exists (a \cdot ((e \circ a) \land f)) \circ ab$. We have $\exists [a \cdot ((e \circ a) \land f)] \circ a$ and $[a \cdot ((e \circ a) \land f)] \circ a = (e \circ a) \land f$. Also, $\exists f \circ b$, so that $\exists ((e \circ a) \land f) \circ b$ and hence

$$\exists [a \cdot ((e \circ a) \land f)] \circ b.$$

From Definition 1.5, we deduce $\exists [a \cdot ((e \circ a) \land f)] \circ ab$. Therefore the binary operation is closed.

We now show the multiplication is associative. Suppose $(e, a), (f, b), (g, c) \in \mathcal{M}(T, \mathcal{Y})$. Then

$$(e, a)[(f, b)(g, c)] = (e, a)(b \cdot ((f \circ b) \land g), bc)
\quad = (a \cdot ((e \circ a) \land b \cdot ((f \circ b) \land g))), abc).$$

As $\exists b \cdot ((f \circ b) \land g)$, Condition (B) gives $\exists (b \cdot ((f \circ b) \land g)) \circ b$ and so

$$\exists ((e \circ a) \land b \cdot ((f \circ b) \land g))) \circ b.$$

Then by Condition (A),

$$\exists b \cdot ((e \circ a) \land (b \cdot ((f \circ b) \land g))) \circ b$$

and

$$b \cdot ((e \circ a) \land (b \cdot ((f \circ b) \land g))) \circ b) = (e \circ a) \land (b \cdot ((f \circ b) \land g)).$$

So,

$$(e, a)[(f, b)(g, c)] = (a \cdot (b \cdot ((e \circ a) \land (b \cdot ((f \circ b) \land g)))) \circ b), abc)
\quad = (ab \cdot ((e \circ a) \land (b \cdot ((f \circ b) \land g)))) \circ b), abc).$$

We also have $f \circ b \land g \leq f \circ b$ and so by Condition (A),

$b \cdot (f \circ b) \land g \leq b \cdot (f \circ b) = f.$

Using Proposition 4.1,

$$(e \circ a) \land (b \cdot ((f \circ b) \land g))) \circ b = (e \circ a) \land (f \cdot (b \cdot ((f \circ b) \land g))) \circ b
= (((e \circ a) \land f) \circ b) \land (b \cdot ((f \circ b) \land g)) \circ b)
= (((e \circ a) \land f) \circ b) \land ((f \circ b) \land g).$$

So,

$$(e, a)[(f, b)(g, c)] = (ab \cdot (((e \circ a) \land f) \circ b) \land ((f \circ b) \land g)), abc)
\quad = (ab \cdot (((e \circ a) \land f) \circ b) \land g), abc)$$

as $\circ$ is order preserving.
We have \((e, a)(f, b) \in \mathcal{M}(T, \gamma)\), \(\exists a \cdot ((e \circ a) \wedge f)\) and so by Condition (B),
\(\exists (a \cdot ((e \circ a) \wedge f)) \circ a \text{ and } (a \cdot ((e \circ a) \wedge f)) \circ a = (e \circ a) \wedge f\). So,
\[
((e \circ a) \wedge f) \circ b \wedge g = (((a \cdot ((e \circ a) \wedge f)) \circ a) \circ b) \wedge g
= ((a \cdot ((e \circ a) \wedge f)) \circ ab) \wedge \gamma.
\]

Hence
\[
(e, a)(f, b)(g, c) = (ab \cdot (((a \cdot ((e \circ a) \wedge f)) \circ ab) \wedge g), abc)
= (a \cdot ((e \circ a) \wedge f), ab)(g, c)
= [(e, a)(f, b)](g, c).
\]

Therefore \(\mathcal{M}(T, \gamma)\) is a semigroup.

It is easy to see that
\[
E = \{(e, 1) \mid e \in \gamma\}
\]
is a semilattice isomorphic to \(\gamma\).

We define unary operations of \(\circ\) and \(\cdot\) on \(\mathcal{M}\) by
\[
(e, a)^+ = (e, 1) \text{ and } (e, a)^* = (e \circ a, 1).
\]

Clearly \(\mathcal{M}\) satisfies the identities
\[
x^+x = x, \quad x^+y^+ = y^+x^+, \quad x^*y^* = y^*x^*, \quad (x^+)^* = x^+ \text{ and } (x^*)^* = x^*.
\]

Let \((e, a), (f, b) \in \mathcal{M}\). Then
\[
((e, a)^+)(f, b)^+ = ((e, 1)(f, b))^+ = (e \wedge f, b)^+ = (e \wedge f, 1) = (e, 1)(f, 1) = (e, a)^+(f, b)^+,
\]
and
\[
((e, a)(f, b))^+(e, a) = (a \cdot (e \circ a \wedge f), ab)^+(e, a)
= (a \cdot (e \circ a \wedge f), 1)(e, a)
= (a \cdot ((e \circ a) \wedge f) \wedge e, a)
= (a \cdot ((e \circ a) \wedge f), a) \quad \text{ as } a \cdot ((e \circ a) \wedge f) \leq a \cdot (e \circ a) = e
\]
\[
= (e, a)(f, 1)
= (e, a)^+(f, b)^+.
\]

so that \(\mathcal{M}\) satisfies \((x^+)^+ = x^+\) and \(xy^+ = (xy)^+x\).

Further,
\[
(e, a)^*(e, a)^* = (e, a)(e \circ a, 1) = (a \cdot (e \circ a \wedge e \circ a), a) = (e, a),
\]
so that \(xx^* = x\) holds, and
\[
((e, a)(f, b)^* = ((e, a)(f \circ b, 1))^* = a \cdot (e \circ a \wedge f \circ b), a)^* = (e \circ a \wedge f \circ b, 1) = (e, a)^*(f, b)^*.
\]
so that \((xy)^* \cdot x^*y^* \) holds. Finally,
\[
(f, b)((e, a)(f, b))^* = (f, b)(a \cdot (e \circ a \wedge f), ab)^*
= (f, b)[(a \cdot (e \circ a \wedge f) \circ ab, 1)
= (b \cdot (f \circ b \wedge [a \cdot (e \circ a \wedge f) \circ ab], f)
= (b \cdot (f \circ b \wedge [a \cdot (b \cdot (e \circ a \wedge f) \circ b) \circ ab), b)
= (b \cdot (f \circ b \wedge (e \circ a \wedge f) \circ ab), b)
= (e \circ a \wedge f, b)
= (e \circ a, 1)(f, b)
= (e, a)^*(f, b)^*.
\]

so that \(x^*y = y(xy)^*\) is satisfied and \(\mathcal{M}\) is a restriction semigroup with \(+, \cdot\) and \(E\) as given.

Again, let \((e, a), (f, b) \in \mathcal{M}\). If \(a = b\), then clearly
\[
(e \wedge f, 1)(e, a) = (e \wedge f, 1)(f, b)
\]
so that \((e, a) \sigma_E (f, b)\); conversely, if we are given that \((e, a) \sigma_E (f, b)\), then as \((g, 1)(e, a) = (g, 1)(f, b)\) for some \((g, 1) \in E\), we must have that \(a = b\). It follows that
\[
(e, a) \sigma_E (f, b) \quad \text{ if and only if } \quad a = b
\]
and hence \(\mathcal{M}/\sigma_E \cong T\).
Suppose now that \((e, a), (f, a) \in \mathcal{M}\). If in addition we have that \((e, a) \hat{\circ} (f, a)\), then \((e, 1) = (e, a)^+ = (f, a)^+ = (f, 1)\), so \(e = f\) and \((e, a) = (f, a)\). On the other hand, if we are given that \((e, a) \hat{\circ} (f, a)\), then \((e \circ a, 1) = (e, a)^* = (f, a)^* = (f \circ a, 1)\), so \(e \circ a = f \circ a\). But then
\[
e = a \cdot (e \circ a) = a \cdot (f \circ a) = f
\]
and again, \((e, a) = (f, a)\). It follows that \(\mathcal{M}\) is proper as required.

It is clear that if \(T\) is unipotent, then \(E = E(\mathcal{M})\), so that \(\mathcal{M}\) is weakly ample. If in addition \(T\) is left (right) cancellative, then it is an easy exercise to show that for any element \((e, a) \in \mathcal{M}\), we have that \((e, a)^\circ \mathcal{L}^+(e, a)((e, a)^+ \mathcal{R}^+(e, a))\), so that \(\mathcal{M}\) is right (left) ample. \(\square\)

As we claim that our approach is symmetric, we finish this section with our justification.

**Proposition 4.3.** Let \((T, Y)\) be a strong \(M\)-pair. Then the map \(\theta : \mathcal{M} \to \mathcal{M}'\) given by \((e, a)\theta = (a, e \circ a)\) is an isomorphism.

**Proof.** It is straightforward to show that \(\theta\) is a well-defined bijection, and preserves \(+\) and \(*\). To show that \(\theta\) preserves the binary operation, let \((e, a), (f, b) \in \mathcal{M}\). Then
\[
(e, a)\theta(f, b)\theta = (a, e \circ a)(b, f \circ b) = (ab, (e \circ a \land b \cdot (f \circ b)) \circ b) = (ab, (e \circ a \land f) \circ b) = (ab, ((a \cdot (e \circ a \land f)) \circ a) \circ b) = (ab, (a \cdot (e \circ a \land f)) \circ ab) = (a \cdot (e \circ a \land f), ab)\theta = ((e, a)(f, b))\theta. \quad \square
\]

We end this section with a brief word on the case for proper inverse semigroups. A group \(G\) acts partially on the left of a set \(X\) if it acts partially as a monoid and if, in addition, for any \(g \in G\) and \(x \in X\), if \(\exists g \cdot x\), then \(\exists g^{-1} \cdot (g \cdot x) = x\). Whenever we talk explicitly of groups acting partially, we will assume that the partial action is subject to this extra condition.

**Corollary 4.4.** Let \((G, \cdot)\) be a strong \(M\)-pair where \(G\) is a group. Then \(\mathcal{M}(G, \cdot)\) is a proper inverse semigroup.

**Proof.** We know from **Theorem 4.2** that \(\mathcal{M} = \mathcal{M}(G, \cdot)\) is ample. If \(\exists e \circ g\), we have from the above that \((e \circ g, g^{-1}) \in \mathcal{M}\) and then
\[
(e, g)(e \circ g, g^{-1}) = (g \cdot (e \circ g \land e \circ g), 1) = (e, 1) = (e, g)^+.\text{It follows that }\mathcal{M}\text{ is inverse.} \quad \square
\]

5. A structure theorem for proper restriction semigroups

We now show that any proper restriction semigroup is isomorphic to one constructed as in the previous section. The directness of our proof is influenced by Munn’s approach [20] to the proof of the P-theorem.

**Theorem 5.1.** Every proper restriction semigroup \(S\) is isomorphic to some \(\mathcal{M}(S/\sigma_E, E)\).

**Proof.** Let \(T = S/\sigma_E\). We shall define a partial action of \(T\) on the right of \(E\) by
\[
\exists e \circ ms_E \iff \exists s \in S\text{ with }e = s^+\text{ and }ms_E = s\sigma_E,
\]
in which case
\[
e \circ ms_E = s^+ \circ s\sigma_E = s^*.
\]
This is clearly well-defined, since \(S\) is proper.

For any \(e \in E\), we have that \(e = e^+\) and \(e\sigma_E = 1_T\), so \(\exists e \circ 1_T\) and \(e \circ 1_T = e\).

Suppose \(\exists s^+ \circ s\sigma_E\) and \(\exists (s^+ \circ s\sigma_E) \circ t\sigma_E\). As \(s^+ \circ t\sigma_E\), there must be a \(u \in S\) with \(s^* = u^+\) and \(u\sigma_E = t\sigma_E\). So
\[
(s^+ \circ s\sigma_E) \circ t\sigma_E = s^* \circ t\sigma_E = u^+ \circ u\sigma_E = u^*.
\]

We wish to show that \(\exists s^+ \circ (st)\sigma_E\) and \(s^* = s^+ \circ (st)\sigma_E\). We have \((su)^+ = (su^+) = (ss^*)^+ = s^+\) and similarly \((su)^* = u^*\).

Clearly, \(su\sigma_E st\), so \(\exists s^+ \circ (st)\sigma_E\) and
\[
s^+ \circ (st)\sigma_E = (su)^+ \circ (su)\sigma_E = (su)^* = u^*\text{ as required. Therefore }\circ\text{ is a partial right action.}
\]

We shall show that the domain of each \(z\sigma_E \in T\) is an order ideal. Suppose \(e, f \in E\) with \(e \leq f\) and \(\exists f \circ z\sigma_E\). Then there exists \(s \in S\) with \(s^+ = f\) and \(s\sigma_E z\). Now \((es)^+ = es^+ = ef = e\) and \(es\sigma_E s\sigma_E z\), so \(\exists e \circ z\sigma_E\). Further, from the third identity for *, \((es)^*s^* = (es^*)^+ = (es)^*\), so that
\[
e \circ z\sigma_E = (es)^* \leq s^* = f \circ z\sigma_E,
\]
and the action is order preserving.
From a semigroup is proper inverse if and only if it is isomorphic to some \( S \) be a restriction semigroup with distinguished semilattice \( E \). Then \( S \) has a proper cover of the form

\[
\mathcal{M}(G, \Upsilon) = \mathcal{M}(S/\sigma, E)
\]

where \( G = S/\sigma \) acts partially as a group on \( E \).

Notice that if \( \exists \sigma \cdot e \), then \( \sigma \cdot e = s \cdot e = s^{-1} \cdot s = s^{-1} \cdot s = s^{-1} \cdot s = s^{-1} = s^+ \cdot s = s^+ = ss^{-1} \cdot s = ss^{-1} \cdot s = ss^{-1} = s^+ \cdot s = s^+ = s^+ = s^{-1} = s^{-1} \cdot s = e \). The dual argument finishes the proof. \( \square \)

Since every restriction semigroup has a proper restriction cover, as in [8], we can deduce the following result using \textbf{Theorem 5.1}. However, we now give a direct proof.

\textbf{Theorem 5.4.} Let \( S \) be a restriction semigroup with distinguished semilattice \( E \). Then \( S \) has a proper cover of the form \( \mathcal{M}(T, E) \), for some strong \( M \)-pair \( (T, E) \).
Proof. First we shall consider a restriction monoid $S$. We define ‘partial’ left and right actions of $S$ on $E$ by

\[ \exists s \cdot e \] if and only if $e \leq s^+$, in which case $s \cdot e = (se)^+$

and

\[ \exists e \circ s \] if and only if $e \leq s^+$, in which case $e \circ s = (es)^*$

for $e \in E$ and $s \in S$.

For $e \in E, \exists 1 \cdot e$ as $e \leq 1^* = 1$, and $1 \cdot e = (1e)^+ = e^+ = e$. Similarly $\exists e \circ 1$ and $e \circ 1 = e$. Let $s, t \in S$ and $e \in E$. Suppose $\exists s \cdot e$ and $\exists t \cdot (s \cdot e)$. So, $e \leq s^*, s \cdot e = (se)^+$. We wish to show $\exists t \cdot s \cdot e$ and $t \cdot (s \cdot e) = (t(se)^+)$. We have $\exists t \cdot s \cdot e$. We also have

$$(ts)^* = (tse)^* = (t^*(se)^*)^+ = (((se)^*)^*)^+ = (se)^+ = e^+ \text{ as } (se)^+ \leq t^+$$

$$= s^*e$$

$$= e \text{ as } e \leq s^*.$$

Hence $\exists ts \cdot e$. We also have

$$t \cdot (s \cdot e) = t \cdot (se)^+ = (t(se)^+) = (tse)^+ = ts \cdot e.$$ 

Hence $\bullet$ is a partial left and right action and similarly, $\circ$ is a partial right action.

Let $e, f \in E$ and $s \in S$. Suppose $e \leq f$ and $\exists s \cdot f$, we have $e \leq f \leq s^*$, so $\exists f \cdot s$. Similarly we have the dual for the partial right action, so the domains of each element of $S$ are order ideals.

Let $e, f \in E$ and $s \in S$. Suppose $e \leq f$, $\exists s \cdot f$ and $\exists s \cdot e$, so $f \leq s^*$ and $e \leq s^*$. We wish to show $s \cdot e \leq s \cdot f$, i.e. $(se)^+ \leq (sf)^+$.

We have

$$(se)^+ (sf)^+ = ((sf)^+ se)^+ = ((sf)^+ sfee)^+ = (sf)^+ e = (sf)^+.$$ 

Hence $s \cdot e \leq s \cdot f$. A similar argument holds for the partial right action, so the action of $S$ preserves the partial order in $E$.

Let $e, f \in E$ and $s \in S$. Suppose $\exists s \cdot e$. So, $e \leq s^*$ and $s \cdot e = (se)^+$. We wish to show $\exists (s \cdot e) \circ s$, i.e. $(se)^+ \leq s^*$, and $(s \cdot e) \circ s = e$. We have

$$(se)^+ s^+ = ((se)^+ s^+)^+ = ((se)^+ s^+) = (se)^+.$$ 

So $\exists (s \cdot e) \circ s$. We also have

$$(s \cdot e) \circ s = (se)^+ \circ s = ((se)^+) = (se)^* s^* e = e.$$ 

Dually, Condition (A) holds.

For $s \in S$, we have $s^+ \in E$ which implies $\exists s^+ \circ s$, so $(S, E)$ is a strong M-pair and we can construct the proper restriction semigroup

\[ \mathcal{M} = \mathcal{M}(S, E) = \{(e, s) \in E \times S : \exists e \circ s = \{(e, s) \in E \times S : e \leq s^+\}, \]

with binary operation given by

$$(e, s)(f, t) = (s \cdot ((e \circ s) \wedge f), st) = ((se)^* f)^+, st)$$

for $(e, s), (f, t) \in \mathcal{M}$.

Let us define $\theta : \mathcal{M} \to S$ by $(e, s) \theta = es \circ f$ for $(e, s) \in \mathcal{M}$. For any $s \in S, (s^+, s) \in \mathcal{M}$ and $(s^+, s) \theta = s$, so $\theta$ is onto. We also have

$$((e, s)(f, t))\theta = (es)^* f^+ st = s(es)^* ft = es = (e, s)\theta(f, t)\theta$$

for $(e, s), (f, t) \in \mathcal{M}$. For $(e, s) \in \mathcal{M}$.

$$(e, s)^+ \theta = (e, 1)^+ = e = es^+ = (es)^+ = [(e, s)\theta]^+$$

and

$$(e, s)^* \theta = (e \circ s, 1)^\theta = e \circ s = (es)^* = [(e, s)\theta]^*.$$ 

Clearly $\theta$ is idempotent separating on the distinguished semilattice $E_{\mathcal{M}}$ of $\mathcal{M}$, so $\mathcal{M}$ is a proper cover of $S$.

Now consider a restriction semigroup $S$ with distinguished semilattice $E$. As $S^1$ is a restriction monoid with distinguished semilattice $E^1$.

$$\mathcal{M}' = \mathcal{M}(S^1, E^1) = \{(e, s) \in E^1 \times S^1 : e \leq s^+\}$$

is a proper restriction monoid and $\theta : \mathcal{M}' \to S^1$, as defined above, is a covering morphism.
Let 
\[ \mathcal{N} = \{(e, s) \in E \times S^1 : \exists e \circ s \} = \{(e, s) \in E \times S^1 : e \leq s^+\} \subseteq \mathcal{M}'. \]

Then \( \mathcal{N} \) is a \((2, 1, 1)\)-subalgebra of \( \mathcal{M}' \) as, for \((e, s), (f, t) \in \mathcal{N}\),

\[ (e, s)(f, t) = ((s(es)^*f)^+, st) \in \mathcal{N}, \]
\[ (e, s)^+ = (e, 1) \in \mathcal{N} \]

and

\[ (e, s)^* = (e \circ s, 1) \in \mathcal{N} \]

as \( e \circ s = (es)^* \in S \). Hence \( \mathcal{N} \) is a restriction semigroup with distinguished semilattice \( E_{\mathcal{N}} = \{(e, 1) : e \in E\} = E_{\mathcal{M}} \). As \( \mathcal{M}' \) is proper restriction, it follows that \( \mathcal{N} \) is also proper. As \( \theta \) restricted to \( \mathcal{N} \) is a \((2, 1, 1)\)-morphism mapping to \( S \), and

\[ s = (s^+, s) \theta, (s^+, s) \theta \in \mathcal{N} \theta \]

for any \( s \in S \), we have that \( \mathcal{N} \) is a proper cover for \( S \). It is easy to see that \((S^1, E)\) is a strong M-pair, so that \( \mathcal{N} = \mathcal{M}(S^1, E) \).

\[ \square \]
