Methods: From 105 patients (male gender 79%, age 61.6±11.0 years), the anatomical angiographic grade and direction of collateral flow in 121 totally occluded vessels was compared to the translesional attenuation gradient of vessel distal to total occlusion (TAGdistal) derived from 64-detector row CCTA. TAG is defined as the linear gradient of luminal attenuation along coronary artery, and was validated against angiographic stenosis and flow velocity in our previous study. Results: TAGdistal increased consistently and significantly with the degree of collateral flow, from -4.43±4.02 HU/mm for Rentrop score 0 to 0.82±1.48 HU/mm for Rentrop score 3 (p<0.0001). TAGdistal was also significantly higher in retrograde flow compared to antegrade collateral flow (-2.44±3.04 HU/mm vs. 3.31±4.18 HU/mm, p<0.0001). The already occluded collateral vessel that have Rentrop score 2 or 3, which was found in 42.1% (51/121), could be predicted by the TAGdistal cutoff value of > -1.28 HU/mm with area under receiver operating characteristic curve of 0.689, and with a sensitivity and specificity, positive and negative predictive value of 86.3%, 47.1%, and 54.3%, 82.5%, respectively.

Conclusions: As far as we know, this is the first study showing that CT can evaluate coronary collateral flow. Using TAG method, CCTA appears to be able to measure quantitatively the degree and direction of coronary collateral circulation, and predict angiographically well developed collateral vessels. These abilities of CCTA may be useful for evaluation of patients with complex coronary artery disease.

Background: Coronary angiography (CCTA) has been used to predict procedural success of percutaneous coronary intervention (PCI) for chronic total occlusion (CTO). However, the role of CCTA on the procedural outcome has not been reported in a large-scale study. We investigated the impact of pre-procedural CCTA on the procedural success of CTO PCI on a patient-basis.

Methods: We retrospectively compared 2,840 patients without pre-procedural CCTA (no CCTA group) and 658 patients with CCTA (CCTA group) from e-CTO, a Korean multicenter registry comprising 26 centers. Results were further confirmed in propensity-matched subgroup (N=1,316).

Results: CCTA groups were younger (62.1±10.6 vs. 63.1±11.2, p<0.05), more were females (33.1% vs. 28.5%, p<0.05), more were located in distal segments to re-canalized CTO (65% vs. 47.6%, p<0.001), and more patients had CTO at 3 tertiary PCI centres between January 2004 and December 2011. The J-CTO score was a significant predictor of failure (odds ratio 1.68, 95% CI 1.47 – 1.90, p<0.001). At multivariable logistic regression analysis, J-CTO score was confirmed in covariate-adjusted model (OR 1.68, 95% CI 1.47 – 1.90, p<0.001).

Conclusions: Pre-procedural CCTA did not show beneficial impact on the procedural success of CTO PCI in our multicenter registry. Careful selection or sophisticated CCTA analytic methods would be required to demonstrate the clinical role of pre-procedural CCTA before CTO PCI.

Background: Total chronic occlusions are the final stage of coronary atherosclerosis. Coronary arteries with CTO have shown large plaque burden and negative remodeling of the occluded region and the segments located distal to the occlusion. Quantitative angiographic changes located distal to successfully re-canalized CTO remain unknown at follow-up.

Methods: Ninety-one CTO successfully treated with drug-eluting stents in 86 patients underwent quantitative angiography at baseline and 12-18 months follow-up. Thirty-one lesions were investigated with IVUS. All analyses were performed using software for nitroglycerin. Angiographic changes of were assessed with quantitative coronary angiography as differences in minimal, mean and maximal lumen diameter (MinLD, MeanLD and MaxLD, respectively). Vessel remodeling was assessed with IVUS as changes in lumen, plaque and vessel volume.

Results: At follow-up, MinLD increased 23.9% (from 0.88±0.32 to 1.09±0.35 mm; p<0.01), MeanLD 16.4% (from 1.99±0.44 to 1.85±0.45 mm; p<0.01) and MaxLD 17.1% (from 2.39±0.67 to 2.67±0.70 mm; p<0.01). Lumen enlargement was greater in non-restenotic lesions, small lumen area at baseline and low LDL-cholesterol levels during the study period. By IVUS, lumen increased 26.9% (from 108.1±89.2 to 137.1±115.5 mm2; p<0.001). The vessel increased 12.1% (from 207.1±170.2 to 232±190.6 mm3; p<0.01) and plaque tended to decrease (-3.9%, from 98.9±88.7 to 94.2±89.3 mm3; p=0.07). Small lumen at baseline was related to greater lumen enlargement.

Conclusions: Distal segments to re-canalized CTO show a notable lumen and vessel enlargement with a trend towards of mild plaque regression. Low LDL-cholesterol levels during the study increases lumen enlargement. Angiographic lesions distal to CTO may change and stent implantation must be discouraged.

1ICPS, Nancy, France, 2ICPS, Quincy, France

Background: Introduction The J-CTO score has been shown to predict successful guidewire crossing within 30 minutes in percutaneous coronary intervention (PCI) or percutaneous coronary intervention (PCI) for chronic total occlusion (CTO). We assessed the hypothesis that the J-CTO score is a useful risk score for the prediction of procedural failure of PCI for CTO in a different cohort of patients.

Methods: The study included all consecutive patients undergoing PCI for CTO at 3 tertiary PCI centres between January 2004 and December 2011. The J-CTO score assigns 1 point to each of the following: calcification, bending, blunt stump, occlusion length ≥ 20 mm, and previously failed lesion and classifications lesions (score of 0) or never revascularized (0), intermediate (score of 1), difficult (score of 2), and “very difficult” (score ≥ 3). A multivariable mixed effect logistic regression model to predict success of CTO PCI was developed.

Results: Results A total of 1261 patients, median age 63 yrs-old (25th-75th percentile, 55-72), undergoing PCI for 1418 CTO were included. PCI failure occurred in 410 (28.9%) lesions. Failure rate significantly increased with increasing J-CTO score (13.6%, 24.7%, 37.0%, 44.8%, in the groups with J-CTO score of 0, 1, 2, ≥3, respectively, p<0.001). At multivariable logistic regression analysis, J-CTO score was a significant predictor of failure (odds ratio 1.68, 95% confidence interval CI) 1.43–1.97, p<0.001, for each unit increase in J-CTO score). PSIP was 0.34 and 0.33 in a model containing J-CTO score only, or a model containing J-CTO score and J-CTO score in addition to clinical, procedural variables and vessel site, respectively. The AUC of a model containing J-CTO score only was significantly higher than AUC of a model containing J-CTO score in addition to clinical, procedural variables and vessel site (0.77, 95% CI 0.75-0.80, vs. 0.71, 95% CI 0.69-0.74, p=0.001).

Conclusions: The J-CTO score is an independent predictor of failure of PCI for CTO and has a good predictive accuracy as stand-

TCT-77
Initial and Mid-Term Angiographic Outcomes of Septal Channel Perforation Related to Retrograde Recanalization for Chronic Total Occlusions

Hiroyuki Tanaka1, Kazuhiro Kodaka1, Seiji Habara1, Yasushi Fuku1, Tsuyoshi Goto1, Kazuaki Mitsudo1
1Kurarashi Central Hospital, Kurashiki, Japan

Background: Septal channel perforation occurs rarely in retrograde recanalization via septal channel for chronic total occlusion (CTO) lesions. There has been little data on mid-term angiographic outcomes of septal channel perforation.

Methods: Septal channel from chronic total occlusion site to heart ventricle was created with cardiac tamponade. Septal channel was created and balloon dilatation was performed. Septal channel to coronary artery was created with cardiac tamponade. Septal channel was created and balloon dilatation was performed.

Results: Between October 2005 and December 2011, we performed the retrograde approach in 465 patients with 484 CTO lesions. Of these, the septal channel was usually performed (96% (267/448)). The in-hospital outcomes were no major adverse cardiac events and 1 cardiac tamponade. The incidence of septal channel perforation was 15.4% (41/267). In septal channel perforation cases, we used the coil (n=5), fat tissue (n=2), balloon dilatation (n=3), and protamine (n=15). Of
