#### Abstract

In this paper, we prove that cyclic hamiltonian cycle systems of the complete graph minus a 1-factor, $K_{n}-I$, exist if and only if $n \equiv 2,4(\bmod 8)$ and $n \neq 2 p^{\alpha}$ with $p$ an odd prime and $\alpha \geqslant 1$. © 2007 Elsevier B.V. All rights reserved.

Keywords: Decomposition; Hamiltonian cycle; Complete graph

## 1. Introduction

Throughout this paper, $K_{n}$ will denote the complete graph on $n$ vertices, $K_{n}-I$ will denote the complete graph on $n$ vertices with a 1 -factor $I$ removed (a 1-factor is a 1 -regular spanning subgraph), and $C_{m}$ will denote the $m$-cycle $\left(v_{1}, v_{2}, \ldots, v_{m}\right)$. An $m$-cycle system of a graph $G$ is a set $\mathscr{C}$ of $m$-cycles in $G$ whose edges partition the edge set of $G$. An $m$-cycle system is called hamiltonian if $m=|V(G)|$, where $V(G)$ denotes the vertex set of $G$.

Several obvious necessary conditions for an $m$-cycle system $\mathscr{C}$ of a graph $G$ to exist are immediate: $3 \leqslant m \leqslant|V(G)|$, the degrees of the vertices of $G$ must be even, and $m$ must divide the number of edges in $G$. A survey on cycle systems is given in [13] and necessary and sufficient conditions for the existence of an $m$-cycle system of $K_{n}$ and $K_{n}-I$ were given in $[1,16]$ where it was shown that a $m$-cycle system of $K_{n}$ or $K_{n}-I$ exists if and only if $n \geqslant m$, every vertex of $K_{n}$ or $K_{n}-I$ has even degree, and $m$ divides the number of edges in $K_{n}$ or $K_{n}-I$, respectively.

Throughout this paper, $\rho$ will denote the permutation ( $01 \ldots n-1$ ), so $\langle\rho\rangle=\mathbb{Z}_{n}$, the additive group of integers modulo $n$. An $m$-cycle system $\mathscr{C}$ of a graph $G$ with vertex set $\mathbb{Z}_{n}$ is cyclic if, for every $m$-cycle $C=\left(v_{1}, v_{2}, \ldots, v_{m}\right)$ in $\mathscr{C}$, the $m$-cycle $\rho(C)=\left(\rho\left(v_{1}\right), \rho\left(v_{2}\right), \ldots, \rho\left(v_{m}\right)\right)$ is also in $\mathscr{C}$. An $n$-cycle system $\mathscr{C}$ of a graph $G$ with vertex set $\mathbb{Z}_{n}$ is called a cyclic hamiltonian cycle system. Finding necessary and sufficient conditions for cyclic $m$-cycle systems of $K_{n}$ is an interesting problem and has attracted much attention (see, for example, [2,3,5,6,8,9,11,14,15]). The obvious necessary conditions for a cyclic $m$-cycle system of $K_{n}$ are the same as for an $m$-cycle system of $K_{n}$; that is, $n \geqslant m \geqslant 3$, $n$ is odd (so that the degree of every vertex is even), and $m$ must divide the number of edges in $K_{n}$. However, these

[^0]conditions are not sufficient. For example, it is not difficult to see that there is no cyclic decomposition of $K_{15}$ into 15 -cycles. Also, if $p$ is an odd prime and $\alpha \geqslant 2$, then $K_{p^{\alpha}}$ cannot be decomposed cyclically into $p^{\alpha}$-cycles [6].

The existence question for cyclic $m$-cycle systems of $K_{n}$ has been completely settled in a few small cases, namely $m=3$ [12], 5 and 7 [15]. For even $m$ and $n \equiv 1(\bmod 2 m)$, cyclic $m$-cycle systems of $K_{n}$ are constructed for $m \equiv$ $0(\bmod 4)$ in [11] and for $m \equiv 2(\bmod 4)$ in [14]. Both of these cases are handled simultaneously in [8]. For odd $m$ and $n \equiv 1(\bmod 2 m)$, cyclic $m$-cycle systems of $K_{n}$ are found using different methods in [2,5,9]. In [3], as a consequence of a more general result, cyclic $m$-cycle systems of $K_{n}$ for all positive integers $m$ and $n \equiv 1(\bmod 2 m)$ with $n \geqslant m \geqslant 3$ are given. Recently, it has been shown [6] that a cyclic hamiltonian cycle system of $K_{n}$ exists if and only if $n \neq 15$ and $n \notin\left\{p^{\alpha} \mid p\right.$ is an odd prime and $\left.\alpha \geqslant 2\right\}$. Thus, as a consequence of a result in [5], cyclic $m$-cycle systems of $K_{2 m k+m}$ exist for all $m \neq 15$ and $m \notin\left\{p^{\alpha} \mid p\right.$ is an odd prime and $\left.\alpha \geqslant 2\right\}$. In [17], the last remaining cases for cyclic $m$-cycle systems of $K_{2 m k+m}$ are settled, i.e., it is shown that, for $k \geqslant 1$, cyclic $m$-cycle systems of $K_{2 k m+m}$ exist if $m=15$ or $m \in\left\{p^{\alpha} \mid p\right.$ is an odd prime and $\left.\alpha \geqslant 2\right\}$. In [19], necessary and sufficient conditions for the existence of cyclic $2 q$-cycle and $m$-cycle systems of the complete graph are given when $q$ is an odd prime power and $3 \leqslant m \leqslant 32$. In [4], cycle systems with a sharply vertex-transitive automorphism group that is not necessarily cyclic are investigated. As a result, it is shown in [4] that no cyclic $k$-cycle system of $K_{v}$ exist if $k<v<2 k$ with $v$ odd and $\operatorname{gcd}(k, v)$ a prime power.

These questions can be extended to the case when $n$ is even by considering the graph $K_{n}-I$. In [3], it is shown that for all integers $m \geqslant 3$ and $k \geqslant 1$, there exists a cyclic $m$-cycle system of $K_{2 m k+2}-I$ if and only if $m k \equiv 0,3(\bmod 4)$. In this paper, we are interested in cyclic hamiltonian cycle systems of $K_{n}-I$ where $n$ is necessarily even. The main result of this paper is the following.

Theorem 1.1. For an even integer $n \geqslant 4$, there exists a cyclic hamiltonian cycle system of $K_{n}-I$ if and only if $n \equiv 2,4(\bmod 8)$ and $n \neq 2 p^{\alpha}$ where $p$ is an odd prime and $\alpha \geqslant 1$.

It is interesting to note that for $n$ even, every cyclic hamiltonian cycle system of $K_{n}-I$ determines a cyclic 1factorization of $K_{n}$. In [10], it is shown that $K_{n}$ has a cyclic 1 -factorization if and only if $n$ is even and $n \neq 2^{t}$ for $t \geqslant 3$.

Our methods involve circulant graphs and difference constructions. In Section 2, we give some basic definitions and lemmas while the proof of Theorem 1.1 is given in Section 3. In Lemma 3.1, we show that if there is a cyclic hamiltonian cycle system of $K_{n}-I$, then $n \equiv 2,4(\bmod 8)$ and $n \neq 2 p^{\alpha}$ where $p$ is an odd prime and $\alpha \geqslant 1$. Lemmas 3.2 and 3.3 handle each of these congruence classes modulo 8 . Our main theorem then follows. For graph theoretic terms not defined in this paper see [18].

## 2. Preliminaries

The proof of Theorem 1.1 uses circulant graphs, which we now define. Let $S$ be a subset of $\mathbb{Z}_{n}$ satisfying
(1) $0 \notin S$, and
(2) $S=-S$; that is, $s \in S$ implies that $-s \in S$.

The circulant $\operatorname{graph} \operatorname{Circ}(n ; S)$ is defined to be that graph whose vertices are the elements of $\mathbb{Z}_{n}$, with an edge between vertices $g$ and $h$ if and only if $h=g+s$ for some $s \in S$. Thus, in this paper, circulant graphs are simple and finite. We call $S$ the connection set, and we will often write $-s$ for $n-s$ when $n$ is understood. Notice that the edge from $g$ to $g+s$ in this graph is generated by both $s$ and $-s$, since $g=(g+s)+(-s)$ and $-s \in S$. Therefore, whenever $S=S^{\prime} \cup-S^{\prime}$, where $S^{\prime} \cap-S^{\prime}=\{s \in S \mid s=-s\}$, every edge of $\operatorname{Circ}(n ; S)$ comes from a unique element of the set $S^{\prime}$. Hence we make the following definition. In a circulant graph $\operatorname{Circ}(n ; S)$, a set $S^{\prime}$ with the property that $S=S^{\prime} \cup-S^{\prime}$ and $S^{\prime} \cap-S^{\prime}=\{s \in S \mid s=-s\}$ is called a set of edge lengths for $\operatorname{Circ}(n ; S)$.

Notice that in order for a graph $G$ to admit a cyclic $m$-cycle decomposition, $G$ must be a circulant graph, so circulant graphs provide a natural setting in which to construct cyclic $m$-cycle decompositions.

The graph $K_{n}$ is a circulant graph, since $K_{n}=\operatorname{Circ}(n ;\{1,2, \ldots, n-1\})$. For $n$ even, $K_{n}-I$ is also a circulant graph, since $K_{n}-I=\operatorname{Circ}(n ;\{1,2, \ldots, n-1\} \backslash\{n / 2\}$ ) (so the edges of the 1 -factor $I$ are of the form $\{i, i+n / 2\}$ for $i=0,1, \ldots,(n-2) / 2)$. In fact, if $n=a^{\prime} b$ and $\operatorname{gcd}\left(a^{\prime}, b\right)=1$, then we can view $\mathbb{Z}_{n}$ as $\mathbb{Z}_{a^{\prime}} \times \mathbb{Z}_{b}$, using the group isomorphism $\phi: \mathbb{Z}_{n} \rightarrow \mathbb{Z}_{a^{\prime}} \times \mathbb{Z}_{b}$ defined by $\phi(k)=\left(k(\bmod a)^{\prime}, k(\bmod b)\right)$. We can therefore relabel both the
vertices and the edge lengths of the circulant graphs, using ordered pairs from $\mathbb{Z}_{a^{\prime}} \times \mathbb{Z}_{b}$, rather than elements of $\mathbb{Z}_{n}$, by identifying elements of $\mathbb{Z}_{n}$ with their images under $\phi$. This will prove a very useful tool in our results. Throughout Section 3, as $n$ is even, we will use the isomorphism $\phi$ with $a^{\prime}=2 a$ for some $a$, and $b$ odd.

Let $H$ be a subgraph of a circulant graph $\operatorname{Circ}(n ; S)$. For a fixed set of edge lengths $S^{\prime}$, the notation $\ell(H)$ will denote the set of edge lengths belonging to $H$, that is,

$$
\ell(H)=\left\{s \in S^{\prime} \mid\{g, g+s\} \in E(H) \text { for some } g \in \mathbb{Z}_{n}\right\} .
$$

Many properties of $\ell(H)$ are independent of the choice of $S^{\prime}$; in particular, neither of the two lemmas in this section depends on the choice of $S^{\prime}$.

Let $C$ be an $m$-cycle in a cyclic decomposition $\mathscr{C}$ of $\operatorname{Circ}(n ; S)$, and recall that the permutation $\rho$, which generates $\mathbb{Z}_{n}$, has the property that $\rho(C) \in \mathscr{C}$ whenever $C \in \mathscr{C}$. We can therefore consider the action of $\mathbb{Z}_{n}$ as a permutation group acting on the elements of $\mathscr{C}$. Viewing matters this way, the length of the orbit of $C$ (under the action of $\mathbb{Z}_{n}$ ) can be defined as the least positive integer $k$ such that $\rho^{k}(C)=C$. Observe that such a $k$ exists since $\rho$ has finite order; furthermore, the well-known orbit-stabilizer theorem (see, for example [7, Theorem $1.4 \mathrm{~A}($ iii $)]$ ) tells us that $k$ divides $n$. Thus, if $G$ is a graph with a cyclic $m$-cycle system $\mathscr{C}$ with $C \in \mathscr{C}$ in an orbit of length $k$, then it must be that $k$ divides $n=|V(G)|$ and that $\rho(C), \rho^{2}(C), \ldots, \rho^{k-1}(C)$ are distinct $m$-cycles in $\mathscr{C}$, where $\rho=(01 \cdots n-1)$.

The next lemma gives many useful properties of an $m$-cycle $C$ in a cyclic $m$-cycle system $\mathscr{C}$ of a graph $G$ with $V(G)=\mathbb{Z}_{n}$ where $C$ is in an orbit of length $k$. Many of these properties are also given in [6] in the case that $m=n$. The proofs of the following statements follow directly from the previous definitions and are therefore omitted.

Lemma 2.1. Let $C=\left(v_{0}, v_{1}, \ldots, v_{m-1}\right)$ be an $m$-cycle in a cyclic $m$-cycle system $\mathscr{C}$ of a graph $G$ of order $n$. Let $C$ be in an orbit of length $k$. Then
(1) $|\ell(C)|=m k / n$,
(2) if $\ell \in \ell(C)$, then $C$ has $n / k$ edges of length $\ell$, and
(3) $(n / k) \mid \operatorname{gcd}(m, n)$.

When $m=n$, let $P: v_{0}=0, v_{1}, \ldots v_{k}$ be a subpath of $C$ of length $k$. Then
(4) for each $\ell \in \ell(C), k \nmid \ell$,
(5) $v_{k}=k x$ for some integer $x$ with $\operatorname{gcd}(x, n / k)=1$,
(6) $v_{1}, v_{2}, \ldots, v_{k}$ are distinct modulo $k$,
(7) $\ell(P)=\ell(C)$, and
(8) $P, \rho^{k}(P), \rho^{2 k}(P), \ldots, \rho^{n-k}(P)$ are pairwise edge-disjoint subpaths of $C$.

A set $X$ of $m$-cycles in a graph $G$ with vertex set $\mathbb{Z}_{n}$ such that $\mathscr{C}=\left\{\rho^{i}(C) \mid C \in X, i=0,1, \ldots, n-1\right\}$ is an $m$-cycle system of $G$ with the property that $C \in X$ implies $\rho^{i}(C) \notin X$ for $1 \leqslant i \leqslant n-1$ is called a complete system of representatives for $\mathscr{C}$. Note that if $X$ is a complete system of representatives for a cyclic $m$-cycle system $\mathscr{C}$ of the graph $\operatorname{Circ}(n ; S)$ and $S^{\prime}$ is a set of edge lengths, then it must be that the collection of sets $\{\ell(C) \mid C \in X\}$ forms a partition of $S^{\prime}$.

## 3. Proof of the main theorem

In this section, we will prove Theorem 1.1. We begin by determining the admissible values of $n$ in Lemma 3.1. Next, for those admissible values of $n$, we construct cyclic hamiltonian cycle systems of $K_{n}-I$ in Lemmas 3.2 and 3.3. The strategy we will adopt is as follows. For $n$ even, we will choose integers $a$ and $b$ so that $n=2 a b$ with $b$ odd and $\operatorname{gcd}(a, b)=1$. We will then view $K_{n}-I$ as a circulant graph labelled by the elements of $\mathbb{Z}_{2 a} \times \mathbb{Z}_{b}$. Recall that $\phi: \mathbb{Z}_{n} \rightarrow \mathbb{Z}_{a^{\prime}} \times \mathbb{Z}_{b}$, is defined by $\phi(k)=\left(k(\bmod a)^{\prime}, k(\bmod b)\right)$, where here $a^{\prime}=2 a$. Let

$$
S^{\prime}=\{(0, j),(a, j) \mid 1 \leqslant j \leqslant(b-1) / 2\} \cup\{(i, k) \mid 1 \leqslant i \leqslant a-1,0 \leqslant k \leqslant b-1\},
$$

and observe that $\left|S^{\prime}\right|=(b-1)+(a-1) b=a b-1=(n-2) / 2$. Now $S^{\prime} \cap-S^{\prime}=\emptyset$, so that $\operatorname{Circ}\left(n ; \phi^{-1}\left(S^{\prime} \cup-S^{\prime}\right)\right)$ is an $(n-2)$-regular graph so indeed $\operatorname{Circ}\left(n ; \phi^{-1}\left(S^{\prime} \cup-S^{\prime}\right)\right)=K_{n}-I$, and $\phi^{-1}\left(S^{\prime}\right)$ is a set of edge lengths of $K_{n}-I$, which becomes the set $S^{\prime}$ under relabelling.

Let $\hat{\rho}=\phi \rho \phi^{-1}$ and note that

$$
\hat{\rho}=((0,0)(1,1)(2,2) \cdots(2 a-1, b-1))
$$

generates $\mathbb{Z}_{2 a} \times \mathbb{Z}_{b}$, that is, $\langle\hat{\rho}\rangle=\mathbb{Z}_{2 a} \times \mathbb{Z}_{b}$. Let $\mathscr{C}$ be an $m$-cycle system of $K_{n}-I$ where the vertices have been labelled by the elements of $\mathbb{Z}_{2 a} \times \mathbb{Z}_{b}$ such that $C \in \mathscr{C}$ implies $\hat{\rho}(C) \in \mathscr{C}$. Then, clearly $\left\{\phi^{-1}(C) \mid C \in \mathscr{G}\right\}$ is a cyclic $m$-cycle system of $K_{n}-I$ with vertex set $\mathbb{Z}_{n}$.
Next observe that if $(e, f) \in S^{\prime}$ has $\operatorname{gcd}(e, 2 a)=1$ and $\operatorname{gcd}(f, b)=1$, then $\operatorname{Circ}\left(n ;\left\{ \pm \phi^{-1}((e, f))\right\}\right)$, the graph with vertex set $\mathbb{Z}_{n}$ consisting of the edges of length $\pm \phi^{-1}((e, f))$, forms an $n$-cycle $C$ with the property that $\rho(C)=C$. Let

$$
T=\left\{(i, j) \in S^{\prime} \mid \operatorname{gcd}(i, 2 a)>1 \text { or } \operatorname{gcd}(j, b)>1\right\}
$$

To find a cyclic hamiltonian cycle system of $K_{n}-I$, it suffices to find a set $X$ of $n$-cycles such that $\{\ell(C) \mid C \in X\}$ is a partition of $T$. Then the collection

$$
\mathscr{C}=\left\{\phi^{-1}(C), \rho\left(\phi^{-1}(C)\right), \ldots, \rho^{n-1}\left(\phi^{-1}(C)\right) \mid C \in X\right\} \cup\left\{\operatorname{Circ}\left(n ;\left\{ \pm \phi^{-1}((e, f))\right\}\right) \mid(e, f) \in S^{\prime} \backslash T\right\}
$$

is a cyclic hamiltonian cycle system of $K_{n}-I$.
We now show that if $K_{n}-I$ has a cyclic hamiltonian cycle system for $n$ even, then $n \geqslant 4$ with $n \equiv 2,4(\bmod 8)$ and $n \neq 2 p^{\alpha}$ where $p$ is an odd prime and $\alpha \geqslant 1$.

Lemma 3.1. For an even integer $n \geqslant 4$, if there exists a cyclic hamiltonian cycle system of $K_{n}-I$, then $n \equiv 2,4(\bmod 8)$ and $n \neq 2 p^{\alpha}$ where $p$ is an odd prime and $\alpha \geqslant 1$.

Proof. Let $n \geqslant 4$ be an even integer and suppose that $K_{n}-I$ has a cyclic hamiltonian cycle system $\mathscr{C}$. Let $X$ be a complete system of representatives for $\mathscr{C}$ and let $C \in X$ be in an orbit of length $k$. Let $P: 0, v_{1}, v_{2}, \ldots, v_{k}=j k$ be a subpath of $C$, starting at vertex 0 , of length $k$. Clearly, if $k$ is even, then $j k \equiv k(\bmod 2)$. On the other hand, if $k$ is odd, then $n / k$ is even and since $\operatorname{gcd}(j, n / k)=1$, it follows that $j$ is odd and hence $j k \equiv k(\bmod 2)$. Let $\ell_{0}(C)$ be the set of even elements in $\ell(C)$ and let $\ell_{1}(C)$ be the set of odd elements in $\ell(C)$. Clearly $\left|\ell_{1}(C)\right| \equiv j k(\bmod 2)$. Then $\left|\ell_{0}(C)\right|+\left|\ell_{1}(C)\right|=k$ and $\left|\ell_{1}(C)\right| \equiv k(\bmod 2)$ implies that $\left|\ell_{0}(C)\right|$ must be even. Thus, if $C \in X$, then $\ell(C)$ has an even number of even edge lengths. Since $\{\ell(C) \mid C \in X\}$ is a partition of $\{1,2, \ldots,(n-2) / 2\}$, it follows that there must be an even number of even integers in the set $\{1,2, \ldots,(n-2) / 2\}$. Since $n$ is even, we have that $n \equiv 2,4(\bmod 8)$.

It remains to show that $n \neq 2 p^{\alpha}$ where $p$ is an odd prime and $\alpha \geqslant 1$. Suppose, to the contrary, that $n=2 p^{\alpha}$ for some odd prime $p$ and $\alpha \geqslant 1$. Let $X$ be a complete system of representatives for $\mathscr{C}$ and choose $C \in X$ with $2 p^{\alpha-1} \in \ell(C)$ (replace $S^{\prime}$ by $-S^{\prime}$ if necessary to ensure that $2 p^{\alpha-1} \in S^{\prime}$; since $p \neq 2,2 p^{\alpha-1}$ is not the length of the edges in the missing 1 -factor $I$ ). Suppose that $C$ is in an orbit of length $k$. Then $k \mid 2 p^{\alpha}$, and since $K_{n}-I$ has $2 p^{\alpha}\left(2 p^{\alpha}-2\right) / 2$ edges and each cycle of $\mathscr{C}$ has $2 p^{\alpha}$ edges, we must have $|\mathscr{C}|=p^{\alpha}-1$. It therefore follows that $1 \leqslant k<2 p^{\alpha}$. Hence, $k \mid 2 p^{\alpha-1}$, and by Lemma 2.1, we must have $k=1$. But if $k=1$, then $\ell(C)=\left\{2 p^{\alpha-1}\right\}$ and since $\operatorname{Circ}\left(2 p^{\alpha} ;\left\{ \pm 2 p^{\alpha-1}\right\}\right)$ consists of $2 p^{\alpha-1} p$-cycles, we have a contradiction. Therefore, $n \neq 2 p^{\alpha}$ where $p$ is an odd prime and $\alpha \geqslant 1$.

We will handle each of the cases $n \equiv 2(\bmod 8)$ and $n \equiv 4(\bmod 8)$ separately. We begin with the case $n \equiv 4(\bmod 8)$ as this is the easier of the two cases.

Lemma 3.2. For $n \equiv 4(\bmod 8)$, the graph $K_{n}-I$ has a cyclic hamiltonian cycle system.
Proof. Suppose that $n \equiv 4(\bmod 8)$, say $n=8 q+4$ for some nonnegative integer $q$. Since $K_{4}-I$ is a 4 -cycle, we may assume that $q \geqslant 1$. Now, $\mathbb{Z}_{n} \cong \mathbb{Z}_{4} \times \mathbb{Z}_{2 q+1}$ and thus we will use $\phi$ to relabel the vertices of $K_{n}-I=\operatorname{Circ}(n ;\{1, \ldots, n-$ $1\} \backslash\{n / 2\})$ with the elements of $\mathbb{Z}_{4} \times \mathbb{Z}_{2 q+1}$. The set

$$
S^{\prime}=\{(0, i),(2, i) \mid 1 \leqslant i \leqslant q\} \cup\{(1, j) \mid 0 \leqslant j \leqslant 2 q\}
$$

has the property that $S^{\prime} \cap-S^{\prime}=\emptyset$ and $\phi^{-1}\left(S^{\prime} \cup-S^{\prime}\right)=\{1,2, \ldots, n-1\} \backslash\{n / 2\}$. Thus we can think of the elements of $S^{\prime}$ as the edge lengths of the relabelled graph. If $q$ is even, say $q=2 j$ for some positive integer $j$, define the walk $P$ by

$$
\begin{aligned}
& P:(0,0),(0,1),(0,-1),(0,2),(0,-2), \ldots,(0, j),(0,-j) \\
& \quad(2, j+1),(0,-(j+1)),(2, j+2),(0,-(j+2)), \ldots,(2, q),(0,-q),(1,0) .
\end{aligned}
$$

If $q$ is odd, say $q=2 j+1$ for some nonnegative integer $j$, define the walk $P$ by

$$
\begin{gathered}
P:(0,0),(0,1),(0,-1),(0,2),(0,-2), \ldots,(0, j),(0,-j),(0, j+1), \\
\\
(2,-(j+1)),(0, j+2),(2,-(j+2)), \ldots,(0, q),(2,-q),(3,0)
\end{gathered}
$$

In either case, note that the vertices of $P$, except for the first and the last, are distinct modulo $2 q+1$ in the second coordinate, while the first and the last vertices are distinct modulo 4 in the first coordinate. Therefore, $P$ is a path. Next, the edge lengths of $P$, in the order they are encountered, are $(0,1),(0,2), \ldots,(0, q),(2, q),(2, q-1), \ldots,(2,1)$, $(1, q)$. Let

$$
C=P \cup \hat{\rho}^{2 q+1}(P) \cup \hat{\rho}^{4 q+2}(P) \cup \hat{\rho}^{6 q+3}(P) .
$$

Then, clearly $C$ is an $n$-cycle in an orbit of length $2 q+1$ and

$$
\ell(C)=\{(0,1),(0,2), \ldots,(0, q),(2, q),(2, q-1), \ldots,(2,1),(1, q)\}
$$

Now, let $d_{0}, d_{1}, \ldots, d_{t}$ denote the integers with $0 \leqslant d_{j}<2 q$ and $\operatorname{gcd}\left(d_{j}, 2 q+1\right)>1$. For $j=0,1, \ldots, t$, consider the walk $P_{j}:(0,0),\left(1, d_{j}\right),(2,2 q)$. Clearly, $P_{j}$ is a path and the edge lengths of $P_{j}$, in the order they are encountered, are $\left(1, d_{j}\right),\left(1,2 q-d_{j}\right)$. Let

$$
C_{j}=P_{j} \cup \hat{\rho}^{2}\left(P_{j}\right) \cup \hat{\rho}^{4}\left(P_{j}\right) \cup \hat{\rho}^{6}(P-j) \cup \cdots \hat{\rho}^{8 q+2}\left(P_{j}\right) .
$$

Then $C_{j}$ is an $n$-cycle in an orbit of length 2 and

$$
\ell\left(C_{j}\right)=\left\{\left(1, d_{j}\right),\left(1,2 q-d_{j}\right)\right\}
$$

Since $\operatorname{gcd}(q, 2 q+1)=1$, we have that $d_{j} \neq q$ and thus $\ell(C) \cap \ell\left(C_{j}\right)=\emptyset$ for $0 \leqslant j \leqslant t$.
Let $T=\left\{\ell(C), \ell\left(C_{0}\right), \ldots, \ell\left(C_{t}\right)\right\}$, and let $(e, f) \in S^{\prime} \backslash T$. Then $e=1$ and $\operatorname{gcd}(f, 2 q+1)=1$. Thus,

$$
X=\left\{\phi^{-1}(C), \phi^{-1}\left(C_{0}\right), \ldots, \phi^{-1}\left(C_{t}\right)\right\} \cup\left\{\operatorname{Circ}\left(n ;\left\{ \pm \phi^{-1}((e, f))\right\}\right) \mid(e, f) \in S^{\prime} \backslash T\right\}
$$

is a complete system of representatives for a cyclic hamiltonian cycle system of $K_{n}-I$.
Before continuing, let $\Phi$ denote the Euler-phi function, that is, for a positive integer $a, \Phi(a)$ denotes the number of integers $r$ with $1 \leqslant r \leqslant a$ and $\operatorname{gcd}(r, a)=1$. For a positive integer $a, \Phi(a)$ is easily computed from the prime factorization of $a$. Let $a=p_{1}^{k_{1}} p_{2}^{k_{2}} \cdots p_{t}^{k_{t}}$ where $p_{1}, p_{2}, \ldots, p_{t}$ are distinct primes and $k_{1}, k_{2}, \ldots, k_{t}$ are positive integers. Then

$$
\Phi(a)=\prod_{i=1}^{t} p_{i}^{k_{i}-1}\left(p_{i}-1\right)
$$

We now handle the case when $n \equiv 2(\bmod 8)$.
Lemma 3.3. For $n \equiv 2(\bmod 8)$ with $n \geqslant 4$ and $n \neq 2 p^{\alpha}$ where $p$ is an odd prime and $\alpha \geqslant 1$, the graph $K_{n}-I$ has a cyclic hamiltonian cycle system.

Proof. Suppose that $n \equiv 2(\bmod 8)$ with $n \neq 2 p^{\alpha}$ where $p$ is an odd prime and $\alpha \geqslant 1$, say $n=8 q+2$ for some positive integer $q$. Let $4 q+1=p_{1}^{k_{1}} p_{2}^{k_{2}} \cdots p_{r}^{k_{r}} q_{1}^{j_{1}} q_{2}^{j_{2}} \cdots q_{s}^{j_{s}}$ where $p_{1}, p_{2}, \ldots, p_{r}, q_{1}, q_{2}, \ldots, q_{s}$ are all distinct primes with $r, s \geqslant 0 ; p_{1}<p_{2}<\cdots<p_{r} ; p_{i} \equiv 3(\bmod 4), k_{i} \geqslant 1$ for $1 \leqslant i \leqslant r ; q_{m} \equiv 1(\bmod 4)$, and $j_{m} \geqslant 1$ for $1 \leqslant m \leqslant s$. Since $n \equiv 2(\bmod 8)$, it follows that $\sum k_{i}$ is even.

Case 1. Suppose that $s \geqslant 1$, or some $k_{i}$ is even for $1 \leqslant i \leqslant r$, or $r>2$. Let

$$
a= \begin{cases}q_{1}^{j_{1}} & \text { if } s \geqslant 1, \\ p_{i}^{k_{i}} & \text { if } s=0 \text { and } k_{i} \text { is even for some } 1 \leqslant i \leqslant r, \text { or } \\ p_{2}^{k_{2}} p_{3}^{k_{3}} & \text { if } s=0, k_{i} \text { is odd for } 1 \leqslant i \leqslant r, \text { and } r>2\end{cases}
$$

Note that for each choice of $a$, we have that $a \equiv 1(\bmod 4)$. Let $b=(4 q+1) / a$ and observe that $\operatorname{gcd}(a, b)=1$. Next, we will use $\phi$ to relabel the vertices of $K_{n}-I=\operatorname{Circ}(n ;\{1, \ldots, n-1\} \backslash\{n / 2\})$ with the elements of $\mathbb{Z}_{2 a} \times \mathbb{Z}_{b}$. The set

$$
S^{\prime}=\{(0, j),(a, j) \mid 1 \leqslant j \leqslant(b-1) / 2\} \cup\{(i, j) \mid 1 \leqslant i \leqslant a-1,0 \leqslant j \leqslant b-1\}
$$

has the property that $S^{\prime} \cap-S^{\prime}=\emptyset$ and $\phi^{-1}\left(S^{\prime} \cup-S^{\prime}\right)=\{1,2, \ldots, n-1\} \backslash\{n / 2\}$, so we can think of the elements of $S^{\prime}$ as the edge lengths of the relabelled graph.

Let $d_{1}, d_{2}, \ldots, d_{t}$ denote the integers with $1 \leqslant d_{j}<a$ and $\operatorname{gcd}\left(d_{j}, 2 a\right)>1$ and let $e_{1}, e_{2}, \ldots, e_{a-1-t}$ denote the integers in the set $\{1,2, \ldots, a-1\} \backslash\left\{d_{1}, d_{2}, \ldots, d_{t}\right\}$ so that $\operatorname{gcd}\left(e_{i}, 2 a\right)=1$ for $1 \leqslant i \leqslant a-1-t$. We will need to show that $2(a-1-t) \geqslant t+1$.

First, $\Phi(2 a)$ is the number of integers $r$ with $1 \leqslant n \leqslant 2 a$ and $\operatorname{gcd}(r, 2 a)=1$. Thus, $2 a-\Phi(2 a)$ is the number of integers $r$ with $1 \leqslant r \leqslant 2 a$ and $\operatorname{gcd}(r, 2 a)>1$ so that $(2 a-\Phi(2 a)) / 2$ is the number of integers $r$ with $1 \leqslant r \leqslant a$ and $\operatorname{gcd}(r, 2 a)>1$. Hence $t=(2 a-\Phi(2 a)) / 2-1$, since each $d_{i}<a$. Substituting $t=(2 a-\Phi(2 a)) / 2-1$ into $2(a-1-t) \geqslant t+1$, we obtain the inequality $\Phi(2 a) \geqslant 2 a / 3$, which needs to be verified for each choice of $a$ above. Suppose first that $a=q_{1}^{j_{1}}$. Then, since $q_{1} \geqslant 5>3$ and $\Phi(2 a)=q_{1}^{j_{1}-1}\left(q_{1}-1\right)$, it easily follows that $\Phi(2 a) \geqslant 2 a / 3$. Similarly, if $a=p_{i}^{k_{i}}$, then again $\Phi(2 a) \geqslant 2 a / 3$ since $p_{i} \geqslant 3$. Next suppose that $a=p_{2}^{k_{2}} p_{3}^{k_{3}}$ and observe that since $p_{3}>p_{2}>p_{1}$, it follows that $p_{2} \geqslant 7$ and $p_{3} \geqslant 11$. Now $\Phi(2 a) \geqslant 2 a / 3$ is equivalent to $\Phi(2 a) / a \geqslant 2 / 3$, and since $\Phi(2 a)=p_{2}^{k_{2}-1}\left(p_{2}-1\right) p_{3}^{k_{3}-1}\left(p_{3}-1\right)$, it follows that $\Phi(2 a) / a=\left(p_{2}-1\right)\left(p_{3}-1\right) /\left(p_{2} p_{3}\right) \geqslant 60 / 77>2 / 3$. Hence, $\Phi(2 a) \geqslant 2 a / 3$ if $a=p_{2}^{k_{2}} p_{3}^{k_{3}}$.

Let $b=2 m+1$ for some positive integer $m$. Since $b=(4 q+1) / a$ and $a \equiv 1(\bmod 4)$, we also have $b \equiv 1(\bmod 4)$, so $m$ is even. Say $m=2 j$ for some positive integer $j$, and define the walk $P$ by

$$
\begin{aligned}
& P:(0,0),(0,1),(0,-1),(0,2),(0,-2), \ldots,(0, j),(0,-j) \\
& \quad(a, j+1),(0,-(j+1)),(a, j+2),(0,-(j+2)), \ldots,(a, m),(0,-m),\left(e_{1}, 0\right)
\end{aligned}
$$

Note that the vertices of $P$, except for the first and the last, are distinct modulo $b$ in the second coordinate, while the first and the last vertices are distinct modulo $2 a$ in the first coordinate. Therefore, $P$ is a path. Next, the edge lengths of $P$, in the order they are encountered, are $(0,1),(0,2), \ldots,(0, m),(a, m),(a, m-1), \ldots,(a, 1),\left(e_{1}, m\right)$. Let

$$
C=P \cup \hat{\rho}^{b}(P) \cup \hat{\rho}^{2 b}(P) \cup \cdots \hat{\rho}^{(2 a-1) b}(P) .
$$

Since the last vertex of $P$ is $\left(e_{1}, 0\right)$, and $\operatorname{gcd}\left(e_{1}, 2 a\right)=1$, we have that $C$ is an $n$-cycle in an orbit of length $b$ where

$$
\ell(C)=\left\{(0,1),(0,2), \ldots,(0, m),(a, m),(a, m-1), \ldots,(a, 1),\left(e_{1}, m\right)\right\}
$$

Now, define the walks $P_{1}, P_{2}, \ldots, P_{t}$ as follows for $i=1,3,5, \ldots$,

$$
P_{i}:(0,0),\left(d_{i}, 1\right),(0,-1),\left(d_{i}, 2\right),(0,-2), \ldots,\left(d_{i}, m\right),(0,-m),\left(-e_{(i+1) / 2}, 0\right),
$$

and

$$
P_{i+1}:(0,0),\left(d_{i+1}, 1\right),(0,-1),\left(d_{i+1}, 2\right),(0,-2), \ldots,\left(d_{i+1}, m\right),(0,-m),\left(e_{(i+1) / 2+1}, 0\right)
$$

For $j=1,2, \ldots, t$, the vertices of $P_{j}$, except for the first and the last, are distinct modulo $b$ in the second coordinate, while the first and the last vertices are distinct modulo $2 a$ in the first coordinate. Therefore, each $P_{j}$ is a path. Next, the edge lengths of $P_{j}$, in the order they are encountered, are $\left(d_{j}, 1\right),\left(d_{j}, 2\right), \ldots,\left(d_{j}, m\right),\left(d_{j}, m+1\right), \ldots,\left(d_{j}, b-1\right)$, and $\left(e_{(j+1) / 2}, m+1\right)$ if $j$ is odd or $\left(e_{j / 2+1}, m\right)$ if $j$ is even. Let

$$
C_{j}=P_{j} \cup \hat{\rho}^{b}\left(P_{j}\right) \cup \hat{\rho}^{2 b}\left(P_{j}\right) \cup \cdots \hat{\rho}^{(2 a-1) b}\left(P_{j}\right)
$$

Since the last vertex $(k, 0)$ of $P_{j}$, where $k=-e_{(j+1) / 2}$ or $k=e_{j / 2+1}$ has the property that $\operatorname{gcd}(k, 2 a)=1$, we have that $C_{j}$ is an $n$-cycle in an orbit of length $b$ where

$$
\ell\left(C_{j}\right)=\left\{\left(d_{j}, 1\right),\left(d_{j}, 2\right), \ldots,\left(d_{j}, m\right),\left(d_{j}, m+1\right), \ldots,\left(d_{j}, b-1\right),\left(e_{(j+1) / 2}, m+1\right)\right\}
$$

if $j$ is odd, or

$$
\ell\left(C_{j}\right)=\left\{\left(d_{j}, 1\right),\left(d_{j}, 2\right), \ldots,\left(d_{j}, m\right),\left(d_{j}, m+1\right), \ldots,\left(d_{j}, b-1\right),\left(e_{j / 2+1}, m\right)\right\}
$$

if $j$ is even.
Define the set $A=\ell(C) \cup \ell\left(C_{1}\right) \cup \ell\left(C_{2}\right) \cup \cdots \cup \ell\left(C_{t}\right)$. Now, $A$ contains $t+1$ elements from the set $\left\{\left(e_{i}, m\right),\left(e_{i}, m+\right.\right.$ $1) \mid 1 \leqslant i \leqslant a-1-t\}$ whose size is $2(a-1-t)$. Since we have seen previously that $2(a-1-t) \geqslant t+1$, it follows that there are enough distinct values of $e_{i}$ to make edge lengths in $A$ distinct, so $|A|=(t+1) b$.

Let $c_{1}, c_{2}, \ldots, c_{x}$ denote the integers with $1 \leqslant c_{j}<b$ and $\operatorname{gcd}\left(c_{j}, b\right)>1$ for $1 \leqslant j \leqslant x$. Fix $j$ with $1 \leqslant j \leqslant x$ and for $i=1,2, \ldots, a-1-t$, consider the walk $P_{i, j}:(0,0),\left(e_{i}, c_{j}\right),\left(2 e_{i}, b-1\right)$. Clearly, $P_{i, j}$ is a path and the edge lengths of $P_{i, j}$, in the order they are encountered, are $\left(e_{i}, c_{j}\right),\left(e_{i}, b-1-c_{j}\right)$. Let

$$
C_{i, j}=P_{i, j} \cup \hat{\rho}^{2}\left(P_{i, j}\right) \cup \hat{\rho}^{4}\left(P_{i, j}\right) \cup \hat{\rho}^{6}\left(P_{i, j}\right) \cup \cdots \hat{\rho}^{2 a b-2}\left(P_{i, j}\right) .
$$

Since $\operatorname{gcd}\left(e_{i}, a\right)=1$, it follows that $C_{i, j}$ is an $n$-cycle in an orbit of length 2 and

$$
\ell\left(C_{i, j}\right)=\left\{\left(e_{i}, c_{j}\right),\left(e_{i}, b-1-c_{j}\right)\right\} .
$$

Define the set

$$
B=\bigcup_{\substack{1 \leqslant i \leqslant a-1-t \\ 1 \leqslant j \leqslant x}} \ell\left(C_{i, j}\right)
$$

We want $A \cap B=\emptyset$. Now, if $A \cap B \neq \emptyset$, then as $\operatorname{gcd}\left(c_{k}, b\right)>1$ for every $k$ and $b=2 m+1$, we cannot have $c_{k}=m$ or $c_{k}=m+1$, so it must be the case that $b-1-c_{k}=m+1$ for some $k$ with $1 \leqslant k \leqslant x$. Thus $c_{k}=(b-3) / 2=m-1$. In this case, for $i=1,2, \ldots, a-1-t$, define $P_{i, k}:(0,0),\left(e_{i}, c_{k}\right),\left(2 e_{i}, m\right)$ and create $C_{i, k}$ as before. Thus

$$
\ell\left(C_{i, k}\right)=\left\{\left(e_{i}, c_{k}\right),\left(e_{i}, 1\right)\right\} .
$$

Since $\operatorname{gcd}\left(2 e_{i}, 2 a\right)=2$, it follows that $C_{i, k}$ will be an $n$-cycle in an orbit of length 2 . Thus $A \cap B=\emptyset$.
Finally, consider the path $P^{\prime}:(0,0),(1,0),(-1,0),(2,0),(-2,0), \ldots,((a-1) / 2,0),(-(a-1) / 2,0),(a, 1)$ and let

$$
C^{\prime}=P^{\prime} \cup \hat{\rho}^{a}\left(P^{\prime}\right) \cup \hat{\rho}^{2 a}\left(P^{\prime}\right) \cup \cdots \cup \hat{\rho}^{a(2 b-1)}\left(P^{\prime}\right)
$$

Since $\operatorname{gcd}(1, b)=1$, we have that $C^{\prime}$ is an $n$-cycle in an orbit of length $a$ and

$$
\ell\left(C^{\prime}\right)=\{(1,0),(2,0), \ldots,(a-1,0),((a+1) / 2, b-1)\} .
$$

Since $a \equiv 1(\bmod 4)$ we have that $\operatorname{gcd}((a+1) / 2,2 a)=1$ and therefore $((a+1) / 2, b-1) \notin A \cup B$.
Let $T=S^{\prime} \backslash\left(A \cup B \cup \ell\left(C^{\prime}\right)\right)$ and let $(e, f) \in T$. Then, it must be that $\operatorname{gcd}(e, 2 a)=1$ and $\operatorname{gcd}(f, b)=1$. Thus,

$$
\begin{aligned}
X=\{ & \phi^{-1}(C), \phi^{-1}\left(C_{1}\right), \ldots \phi^{-1}\left(C_{t}\right), \phi^{-1}\left(C_{1,1}\right), \phi^{-1}\left(C_{1,2}\right), \ldots, \phi^{-1}\left(C_{1, x}\right), \phi^{-1}\left(C_{2,1}\right), \phi^{-1}\left(C_{2,2}\right), \\
& \left.\ldots, \phi^{-1}\left(C_{2, x}\right), \ldots, \phi^{-1}\left(C_{a-1-t, 1}\right), \phi^{-1}\left(C_{a-1-t, 2}\right), \ldots, \phi^{-1}\left(C_{a-1-t, x}\right), \phi^{-1}\left(C^{\prime}\right)\right\}
\end{aligned}
$$

$$
\bigcup\left\{\operatorname{Circ}\left(n ;\left\{ \pm \phi^{-1}((e, f))\right\}\right) \mid(e, f) \in T\right\}
$$

is a complete system of representatives for a cyclic hamiltonian cycle system of $K_{n}-I$.
Case 2. Suppose that $s=0, k_{i}$ is odd for $1 \leqslant i \leqslant r$, and $r=2$. Thus $n=2 p_{1}^{k_{1}} p_{2}^{k_{2}}$ where $k_{1}$ and $k_{2}$ are odd. In this case, we will let $a=p_{1}^{k_{1}}, b=p_{2}^{k_{2}}$ and use $\phi$ to relabel the vertices of $K_{n}-I=\operatorname{Circ}(n ;\{1, \ldots, n-1\} \backslash\{n / 2\})$ with the elements of $\mathbb{Z}_{2 a} \times \mathbb{Z}_{b}$. The set

$$
S^{\prime}=\{(0, j),(a, j) \mid 1 \leqslant j \leqslant(b-1) / 2\} \cup\{(i, j) \mid 1 \leqslant i \leqslant a-1,0 \leqslant j \leqslant b-1\}
$$

has the property that $\phi^{-1}\left(S^{\prime}\right)$ is a set of edge lengths of $K_{n}-I$, so we can think of the elements of $S^{\prime}$ as the edge lengths of the relabelled graph.

Let $d_{1}, d_{2}, \ldots, d_{t}$ denote the integers with $1 \leqslant d_{j}<a$ and $\operatorname{gcd}\left(d_{j}, 2 a\right)>1$ and let $e_{1}, e_{2}, \ldots, e_{a-1-t}$ denote the integers in the set $\{1,2, \ldots, a-1\} \backslash\left\{d_{1}, d_{2}, \ldots, d_{t}\right\}$ so that $\operatorname{gcd}\left(e_{i}, 2 a\right)=1$ for $1 \leqslant i \leqslant a-1-t$. In this case, note that as $p_{1} \equiv 3(\bmod 4)$ and $k_{1}$ is odd, $\operatorname{gcd}((a+1) / 2,2 a)=2$ so that $(a+1) / 2 \in\left\{d_{1}, d_{2}, \ldots, d_{t}\right\}$. Without loss of generality, let $d_{1}=(a+1) / 2$ and $e_{1}=1$.

Since $k_{2}$ is odd and $p_{2} \equiv 3(\bmod 4)$, it follows that $b=p_{2}^{k_{2}}=4 j+3$ for some positive integer $j$. Define the walk $P$ by

$$
\begin{aligned}
P: & (0,0),(0,1),(0,-1),(0,2),(0,-2), \ldots,(0, j),(0,-j),(0, j+1),(a,-(j+1)), \\
& (0, j+2),(a,-(j+2)), \ldots,(0,2 j+1),(a,-(2 j+1)),((3 a+1) / 2,0) .
\end{aligned}
$$

Note that the vertices of $P$, except for the first and the last, are distinct modulo $b$ in the second coordinate, while the first and the last vertices are distinct modulo $2 a$ in the first coordinate. Therefore, $P$ is a path. Next, the edge lengths of $P$, in the order they are encountered, are $(0,1),(0,2), \ldots,(0,2 j+1),(a, 2 j+1),(a, 2 j), \ldots,(a, 1),((a+1) / 2$, $2 j+1)$. Let

$$
C=P \cup \hat{\rho}^{b}(P) \cup \hat{\rho}^{2 b}(P) \cup \cdots \hat{\rho}^{(2 a-1) b}(P) .
$$

Since the last vertex $((3 a+1) / 2,0)$ of $P$ has the property that $\operatorname{gcd}((3 a+1) / 2,2 a)=1$, we have that $C$ is an $n$-cycle in an orbit of length $b$ where

$$
\ell(C)=\{(0,1),(0,2), \ldots,(0,2 j+1),(a, 2 j+1),(a, 2 j), \ldots,(a, 1),((a+1) / 2,2 j+1)\}
$$

Define the walk $P_{1}$ by

$$
\begin{aligned}
P_{1}: & (0,0),((a+1) / 2,1),(0,-1),((a+1) / 2,2),(0,-2), \ldots,((a+1) / 2, j),(0,-j), \\
& (1, j+1),(1-(a+1) / 2,-(j+1)),(1, j+2),(1-(a+1) / 2,-(j+2)), \\
& \ldots,(1,2 j+1),(0,-(2 j+1)),\left(-e_{a-1-t}, 0\right) .
\end{aligned}
$$

If $t \geqslant 3$, for $i=2,3, \ldots, t-1$, define the walk $P_{i}$ by

$$
P_{i}:(0,0),\left(d_{i}, 1\right),(0,-1),\left(d_{i}, 2\right),(0,-2), \ldots,\left(d_{i}, 2 j+1\right),(0,-(2 j+1)),\left(e_{(i+1) / 2}, 0\right),
$$

if $i$ is odd, or

$$
P_{i}:(0,0),\left(d_{i}, 1\right),(0,-1),\left(d_{i}, 2\right),(0,-2), \ldots,\left(d_{i}, 2 j+1\right),(0,-(2 j+1)),\left(-e_{i / 2}, 0\right)
$$

if $i$ is even. If $t \geqslant 2$, define the walk $P_{t}$ by

$$
P_{t}:(0,0),\left(d_{t}, 1\right),(0,-1),\left(d_{t}, 2\right),(0,-2), \ldots,\left(d_{t}, 2 j+1\right),(0,-(2 j+1)),\left(e_{a-1-t}, 0\right) .
$$

For $i=1,2, \ldots, t$, the vertices of $P_{i}$, except for the first and the last, are distinct modulo $b$ in the second coordinate, while the first and the last vertices are distinct modulo $2 a$ in the first coordinate. Therefore, $P_{i}$ is a path. Next, the edge lengths of $P_{i}$ for $i \neq 1$, in the order they are encountered, are $\left(d_{i}, 1\right),\left(d_{i}, 2\right), \ldots,\left(d_{i}, 2 j+1\right),\left(d_{i}, 2 j+2\right), \ldots,\left(d_{i}, b-\right.$ $1)$, and $\left(e_{(i+1) / 2}, 2 j+1\right)$ if $1<i<t$ is odd, $\left(e_{i / 2}, 2 j+2\right)$ if $i<t$ is even, or $\left(e_{a-1-t}, 2 j+1\right)$ if $i=t$. The edge lengths of $P_{1}$, in the order they are encountered, are $((a+1) / 2,1),((a+1) / 2,2), \ldots,((a+1) / 2,2 j),(1,2 j+1),((a+$ 1) $/ 2,2 j+2), \ldots,((a+1) / 2, b-2),(1, b-1)$ and $\left(e_{a-1-t}, 2 j+2\right)$. Let

$$
C_{i}=P_{i} \cup \hat{\rho}^{b}\left(P_{i}\right) \cup \hat{\rho}^{2 b}\left(P_{i}\right) \cup \cdots \hat{\rho}^{(2 a-1) b}\left(P_{i}\right) .
$$

Since the last vertex $(\ell, 0)$ of $P_{i}$ has the property that $\operatorname{gcd}(\ell, 2 a)=1$, we have that $C_{i}$ is an $n$-cycle in an orbit of length $b$ where

$$
\ell\left(C_{i}\right)=\left\{\left(d_{i}, 1\right),\left(d_{i}, 2\right), \ldots,\left(d_{i}, 2 j+1\right),\left(d_{i}, 2 j+2\right), \ldots,\left(d_{i}, b-1\right),\left(e_{(i+1) / 2}, 2 j+1\right)\right\}
$$

if $i$ is odd and $1<i<t$,

$$
\ell\left(C_{i}\right)=\left\{\left(d_{i}, 1\right),\left(d_{i}, 2\right), \ldots,\left(d_{i}, 2 j+1\right),\left(d_{i}, 2 j+2\right), \ldots,\left(d_{i}, b-1\right),\left(e_{i / 2}, 2 j+2\right)\right\}
$$

if $i$ is even and $1<i<t$,

$$
\ell\left(C_{i}\right)=\left\{\left(d_{i}, 1\right),\left(d_{i}, 2\right), \ldots,\left(d_{i}, 2 j\right),(1,2 j+1),\left(d_{i}, 2 j+2\right), \ldots,(1, b-1),\left(e_{a-1-t}, 2 j+2\right)\right\}
$$

if $i=1$, or

$$
\ell\left(C_{i}\right)=\left\{\left(d_{i}, 1\right),\left(d_{i}, 2\right), \ldots,\left(d_{i}, 2 j+1\right),\left(d_{i}, 2 j+2\right), \ldots,\left(d_{i}, b-1\right),\left(e_{a-1-t}, 2 j+1\right)\right\}
$$

if $i=t$ and $t \geqslant 2$.
Define the set $A=\ell(C) \cup \ell\left(C_{1}\right) \cup \ell\left(C_{2}\right) \cup \cdots \cup \ell\left(C_{t}\right)$. Now, $A$ contains $t+1$ elements from the set $\left\{\left(e_{i}, 2 j+\right.\right.$ 1), $\left.\left(e_{i}, 2 j+2\right) \mid 1 \leqslant i \leqslant a-1-t\right\}$ whose size is $2(a-1-t)$. As in Case $1, t=(2 a-\Phi(2 a)) / 2$ where in this case $a=p_{1}^{k_{1}}$, and we need $2(a-1-t) \geqslant t+1$. Since $p_{1} \geqslant 3$, the inequality follows. So there are enough distinct values of $e_{i}$ to make edge lengths in $A$ distinct and therefore $|A|=(t+1) b$.

Let $c_{1}, c_{2}, \ldots, c_{x}$ denote the integers with $1 \leqslant c_{j}<b$ and $\operatorname{gcd}\left(c_{j}, b\right)>1$ for $1 \leqslant j \leqslant x$. Fix $j$ with $1 \leqslant j \leqslant x$ and for $i=1,2, \ldots, a-1-t$, consider the walk $P_{i, j}:(0,0),\left(e_{i}, c_{j}\right),\left(2 e_{i}, b-1\right)$. Clearly, $P_{i, j}$ is a path and the edge lengths of $P_{i, j}$, in the order they are encountered, are $\left(e_{i}, c_{j}\right),\left(e_{i}, b-1-c_{j}\right)$. Let

$$
C_{i, j}=P_{i, j} \cup \hat{\rho}^{2}\left(P_{i, j}\right) \cup \hat{\rho}^{4}\left(P_{i, j}\right) \cup \hat{\rho}^{6}\left(P_{i, j}\right) \cup \cdots \hat{\rho}^{2 a b-2}\left(P_{i, j}\right) .
$$

Since $\operatorname{gcd}\left(e_{i}, a\right)=1$, it follows that $C_{i, j}$ is an $n$-cycle in an orbit of length 2 and

$$
\ell\left(C_{i, j}\right)=\left\{\left(e_{i}, c_{j}\right),\left(e_{i}, b-1-c_{j}\right)\right\} .
$$

Define the set

$$
B=\bigcup_{\substack{1 \leqslant i \leqslant a-1-t \\ 1 \leqslant j \leqslant x}} \ell\left(C_{i, j}\right) .
$$

We want $A \cap B=\emptyset$. Now, if $A \cap B \neq \emptyset$, then as $\operatorname{gcd}\left(c_{k}, b\right)>1$ for every $k$ and $b=4 j+3$, we cannot have $c=2 j+1$ or $c=2 j+2$, so it must be the case that $b-1-c_{k}=2 j+2$ for some $k$ with $1 \leqslant k \leqslant x$. Then $c_{k}=(b-3) / 2$. This implies that $3 \mid p_{2}^{k_{2}}$ since $\operatorname{gcd}\left(c_{k}, p_{2}^{k_{2}}\right)>1$. This is impossible since $p_{2} \geqslant 7$.

Finally, consider the path $P^{\prime}:(0,0),(1,0),(-1,0),(2,0),(-2,0), \ldots,((a-1) / 2,0),(-(a-1) / 2,0),(a, 1)$ and let

$$
C^{\prime}=P^{\prime} \cup \hat{\rho}^{a}\left(P^{\prime}\right) \cup \hat{\rho}^{2 a}\left(P^{\prime}\right) \cup \cdots \cup \hat{\rho}^{a(2 b-1)}\left(P^{\prime}\right)
$$

Since $\operatorname{gcd}(1, b)=1$, it follows that $C^{\prime}$ is an $n$-cycle in an orbit of length $a$ and

$$
\ell\left(C^{\prime}\right)=\{(1,0),(2,0), \ldots,(a-1,0),((a+1) / 2, b-1)\} .
$$

Let $T=S^{\prime} \backslash\left(A \cup B \cup \ell\left(C^{\prime}\right)\right)$ and let $(e, f) \in T$. Then, it must be that $\operatorname{gcd}(e, 2 a)=1$ and $\operatorname{gcd}(f, b)=1$. Thus,

$$
\begin{aligned}
X=\{ & \phi^{-1}(C), \phi^{-1}\left(C_{1}\right), \ldots \phi^{-1}\left(C_{t}\right), \phi^{-1}\left(C_{1,1}\right), \phi^{-1}\left(C_{1,2}\right), \ldots, \phi^{-1}\left(C_{1, x}\right), \phi^{-1}\left(C_{2,1}\right), \phi^{-1}\left(C_{2,2}\right), \\
& \left.\ldots, \phi^{-1}\left(C_{2, x}\right), \ldots, \phi^{-1}\left(C_{a-1-t, 1}\right), \phi^{-1}\left(C_{a-1-t, 2}\right), \ldots, \phi^{-1}\left(C_{a-1-t, x}\right), \phi^{-1}\left(C^{\prime}\right)\right\} \\
& \bigcup\left\{\operatorname{Circ}\left(n ;\left\{ \pm \phi^{-1}((e, f))\right\}\right) \mid(e, f) \in T\right\}
\end{aligned}
$$

is a complete system of representatives for a cyclic hamiltonian cycle system of $K_{n}-I$.
Theorem 1.1 now follows from Lemmas 3.1, 3.2 and 3.3.

## Acknowledgement

The authors would like to thank the referees for their careful reviews of an earlier version of this paper.
