Abstract

Nano-particles were doped into YBCO films as pinning centers by a metal organic deposition (MOD) method using trifluoroacetates. Two types of initial solution with a cation ratio of Y: Ba: Cu = 1: 1.5: 3 were prepared; one with the dispersion of SnO\textsubscript{2} particles with the size of 15-25 nm and the other one with the dispersion of smaller ZrO\textsubscript{2} particles with the size of under 8 nm, then the solution was spin-coated on CeO\textsubscript{2}/Gd\textsubscript{2}Zr\textsubscript{2}O\textsubscript{7}/Hastelloy substrates. The coated films were calcined at 430 °C in oxygen atmosphere and crystallized at 780 °C in low oxygen atmosphere. From the results of X-ray diffraction analysis (XRD), peaks of BaSnO\textsubscript{3} were observed clearly in the YBCO film by the starting solution with SnO\textsubscript{2}. On the other hands, little peaks corresponding to BaZrO\textsubscript{3} were observed in the film by the solution with ZrO\textsubscript{2}. Many CuO segregations were recognized at the surface of SnO\textsubscript{2} doped YBCO film in comparison to the YBCO film with ZrO\textsubscript{2} doping. From these results, it is indicated that most of SnO\textsubscript{2} particles in precursors are react with Ba during heating. Critical current density ($J_C$) of the YBCO films by both solutions showed higher performance than that of pure YBCO film in magnetic fields.

1. Introduction

REBa\textsubscript{2}Cu\textsubscript{3}O\textsubscript{7-δ} (REBCO, RE: rare earth elements) films have high critical current density ($J_C$), high transition temperature ($T_C$), and high irreversibility field ($H_{irr}$) so that these films are expected for applying superconducting wire. Metal organic deposition using trifluoroacetates (TFA-MOD) method is a promising procedure for YBCO films since this method can provide high superconducting properties in a cost-effective process with non-vacuum system [1–4]. However, $J_C$ of YBCO films decreases in magnetic fields ($B$). So, in order to improve $J_C$ in magnetic fields, various methods have been proposed for the introduction of effective artificial pinning centers (APCs) in superconducting films. It has been actually reported that $J_C$-$B$ properties improved for REBCO films with BaZrO\textsubscript{3} particles of about 30 nm in diameter by the TFA-MOD method using a starting solution with dissolved Zr-salts [5-6]. Also, in our previous report, SnO\textsubscript{2} compounds were formed in the YBCO film with the size of about 30 nm by this method using a solution with dispersed SnO\textsubscript{2} particles and acted as pinning centers [7-8]. However, it is important to obtain higher $J_C$ in

magnetic fields for the electric power application, so higher number density of particles with smaller size is considered to be effective pinning centers in this method. In this study, we fabricated YBCO films by a starting solution with \( \text{ZrO}_2 \) particles which have the size of about under 8 nm and investigated the growth process of YBCO film with nanoparticles.

2. Experimental

YBCO films were fabricated by the TFA-MOD process. Starting solutions were prepared by dissolving Y-, Cu-octyl salts, and Ba-trifluoroacetates in an adequate solvent with a total metal ion concentration of 1.3 mol/L. We prepared two kinds of initial solutions which nano-particles were dispersed as pinning centers in; one with the dispersion of \( \text{SnO}_2 \) particles with the size of 15-25 nm, the other one with the dispersion \( \text{ZrO}_2 \) (Yttria-stabilized zirconia) with the size of under 8 nm. These particles were dispersed into the solution with the ratio of 2 mol%. The molar ratio of total metals in the solution is \( \text{Y: Ba: Cu: M (M: Sn, Zr) = 1: 1.5: 3: 0.11} \). These solutions were deposited on \( \text{CeO}_2/\text{Gd}_2\text{Zr}_2\text{O}_7/\text{Hastelloy} \) substrates by a spin coating method at 3000 rpm for 120s. Then, two-step heat treatment was applied to the coated films. In the calcination step, these films were calcined up to 430°C at a heating rate of 5°C/min in oxygen atmosphere with water vapor of 2 vol.%. In order to fabricate thick precursor films, a process of coating and calcination were repeated for 3 times. Then, the calcined films were crystallized at a heating rate of 5°C/min and kept the maximum heating temperature of 780°C for 100 min in humid of 10 vol.% and low oxygen of 1000 ppm. Thickness of YBCO films were about 500-700 nm. Crystallinity of the films was characterized by XRD \( \theta/2\theta \) scan. The surface morphology of films was observed by scanning electron microscopy (SEM) and SEM-EDX (Energy Dispersive X-ray Spectroscopy) to analyze the microstructure and composition of the films. The superconducting properties of YBCO films were measured by a DC four probe method.

3. Results and discussion

3.1. Crystallized phases in YBCO films

The result of XRD \( \theta/2\theta \) scan for YBCO films with 2 mol% nano-particles are shown in Fig 1. The vertical axis in the figure shows peak intensities which divided by the peak intensity of \( \text{CeO}_2 \) (200). The result of pure YBCO film was described as a reference in the figure. The peaks of \( \text{SnO}_2 \) (110), \( \text{BaSnO}_3 \) (110) and \( \text{BaSnO}_3 \) (200) were detected at 26.5°, 30°, and 42.5°, respectively, in \( \text{SnO}_2 \) added YBCO film. In the film with \( \text{ZrO}_2 \) addition, the peaks of \( \text{ZrO}_2 \) (111) and \( \text{BaZrO}_3 \) (200) were detected at 30° and 43°, respectively. In addition, the peak of \( \text{Y}_2\text{Cu}_2\text{O}_5 \) (211) and \( \text{CuO} \) (111) were detected in both films with nano-particles addition at 31° and 35°, respectively.

In order to investigate differences of products in each film, higher concentration of particles were introduced to the starting solution and then YBCO films were fabricated. The result of comparison between 2 mol% particles doped film and 8 mol% doped one is shown in Fig 2. In \( \text{SnO}_2 \) doped films as shown in Fig 2(a), the phases of \( \text{SnO}_2 \), \( \text{BaSnO}_3 \), \( \text{Y}_2\text{Cu}_2\text{O}_5 \), and \( \text{CuO} \) were detected. Among them, large increments of peak intensities for \( \text{BaSnO}_3 \), \( \text{Y}_2\text{Cu}_2\text{O}_5 \) and \( \text{CuO} \)
peak were confirmed as the concentration increase of SnO₂, but no increment was detected in SnO₂ peak. From these results, it is considered that the most of SnO₂ particles were combined with Ba and then changed to BaSnO₃ during heat treatment. While, the phases of ZrO₂, BaZrO₃, Y₂Cu₂O₅, and CuO were detected in the YBCO film ZrO₂ doped as shown in Fig 2(b). Among them, large increment for ZrO₂ peak and small increment for Y₂Cu₂O₅ and CuO peaks were observed with the increase of ZrO₂ addition, but the peak of BaZrO₃ was hardly increased. Thus, it is suggested that many ZrO₂ particles in precursors exist as same composition even after heating.

3.2. Surface morphology

To discuss the surface morphology of YBCO films with nano-particles doped, we observed the surface of YBCO films by SEM. Fig 3 shows the SEM images of surface for YBCO films. In the pure YBCO film as shown in Fig 3(a), c-axis oriented YBCO crystals were observed. In SnO₂ doped film as shown in Fig 3(b), segregation of particles with the diameter of about 1 μm was observed on the surface. On the other hand, segregation of particles was detected slightly on the surface for YBCO film with ZrO₂ addition as shown in Fig 3(c).

![Fig. 3. SEM images of film surface for (a) pure YBCO, (b) YBCO with SnO₂ addition, and (c) YBCO with ZrO₂ addition.](image)

In order to clarify the compositional element for these segregated precipitates as seen in Fig 3(b) and (c), SEM-EDX measurement for element mapping was performed. As shown in Fig 4(a) and (b), Cu oxide is observed where particles existed on the surface of both SnO₂ doped film and ZrO₂ doped one. Especially, much Cu oxide particles were observed for YBCO film with SnO₂ addition. From the results both XRD measurement and surface morphology observation, it can be considered that many CuO particles were remained for YBCO film with SnO₂ addition because of the result of reaction between SnO₂ and Ba during heat treatment. On the other hand, less CuO particles were observed for YBCO film with ZrO₂ addition, suggesting less ZrO₂ react with Ba during heating.

3.3. Superconducting properties

Fig 5 shows $T_C$ values of pure YBCO films and YBCO films with 2 mol% nano-particles. $T_C$ of YBCO films with SnO₂ and ZrO₂ addition were 90.7 K and 91.5 K, respectively, in comparison to pure YBCO film, 91.8 K. It is indicated that no degradation of $T_C$ was recognized in YBCO films by introducing nano-particles.

Fig 6 shows dependences of $J_C$ on magnetic field for pure YBCO film and YBCO films with 2 mol% nano-particles addition in magnetic field applied parallel to c-axis ($B//c$) at 77 K. $J_C$ in self field ($J_C^{self}$) of SnO₂ doped film and ZrO₂ doped one were 2.9 MA/cm² and 3.6 MA/cm², respectively, in comparison to pure YBCO film, 4.5 MA/cm². $J_C$ in 3 T of SnO₂ doped was 0.14 MA/cm², and that of ZrO₂ doped film was 0.07 MA/cm². $J_C$ of both YBCO films with nano-particles added was enhanced in comparison to pure YBCO in low magnetic field. And $J_C$ of SnO₂ doped film was higher than pure YBCO in all magnetic fields. As a result, it is suggested that nano-particles doped in YBCO films acted as pinning centers.
3.4. Growth process of YBCO with nano-particles

According to the previous research [7-8], it was predicted that SnO2 in precursors dissolved temporality during heat treatment and then combined with Ba to be BaSnO3. By based on this predict, it was expected that similar tendency was also seen strongly in the case of smaller particles as the reaction from ZrO2 to BaZrO3. However, as seen in results of Fig 3 and Fig 4, the formation of BaZrO3 was hardly confirmed in case of ZrO2 addition. Therefore, it is considered that BaSnO3 particles were formed not by the process of decomposing SnO2 but by peritectic reaction between SnO2 and Ba during heating.

On the other hand, ZrO2 nano-particles could be expected for introducing smaller APCs in YBCO film. It is under investigating the effect of higher concentration addition of nano-particles into YBCO films and the optimization of crystallization conditions. Also, it is important to observe microstructures for identification of APCs in YBCO films in detail.

4. Conclusion

YBCO films were grown by a MOD process using TFA initial solutions containing nano-particles such as SnO2 and ZrO2 as pinning centers to investigate the growth process of YBCO film with nano-particles. It is considered that most of SnO2 particles in precursors react with Ba and form BaSnO3 during heat treatment. \(J_C\) in magnetic fields of SnO2 doped film was enhanced in comparison to pure YBCO film. In order to obtain higher \(J_C\) in magnetic fields, it is necessary to control doping concentration of nano-particles into YBCO films and to optimize crystallization condition.
