OBJECTIVES: Quality improvement initiatives in acute coronary syndrome (ACS) such as CRUSADE have found marked increase in treatment guideline adherence during the past several years. This descriptive study used time-stamped data to examine pharmacologic treatment and laboratory biomarker utilization patterns in ACS patients who underwent percutaneous coronary intervention (PCI). METHODS: The data source consisted of 19 hospitals throughout the U.S. that used time-stamp data from January 2003—September 2004. ACS was identified in the dataset using ICD-9 diagnosis codes for unstable angina and/or myocardial infarction (MI). The time-stamp allowed more precise measurement of drug administration and biomarker sampling. Biomarker definition of MI was CK-MB >3 times upper limit of normal, troponin I and myoglobin >1 times upper limit of normal.RESULTS: A total of 6,282 ACS patients who had been given clopidogrel were identified with adequate time-stamp information. The most common recorded comorbid diagnoses were ischemic heart disease 91.2%, hypertension 54.4%, lipid disorder 57.9%, and diabetes 21.7%. Aspirin (ASA) plus clopidogrel was received by 75.9% of patients and initiated on the day of PCI in 88.3% of patients. The majority of initial ASA plus clopidogrel administration was minus (−) 10 to plus (+) 14 hours from PCI. GP IIb/IIIa inhibitors were received by 68.6% and statins by 73% of patients, respectively during hospitalization. Post-procedure (>8 hours after PCI) biomarker monitoring (CK-MB, troponin I or myoglobin) was performed in 67.9% of patients. The majority of testing was CK-MB or troponin I. Results suggestive of MI were found in up to 67% of patients. CONCLUSIONS: This novel examination of ACS treatment patterns in ACS patients who underwent PCI. A gap in therapy, defined as late refills >14 days apart, was seen 14 days after PCI. Clopidogrel therapy was 41 days. 74% of patients stopped therapy, defined as not on clopidogrel 28-days prior to end of follow-up. A gap in therapy, defined as late refills >14 days apart, was seen in 89%. Concomitant cardiovascular drug therapies included: calcium channel blocker (20.3%), beta-blocker (69.1%) and statin (64.7%). CONCLUSION: This descriptive study suggests clopidogrel is underutilized in ACS patients and long-term adherence to therapy was poor as demonstrated by stoppages or gaps in therapy.

THIENOPYRIDINE THERAPY IN ACUTE CORONARY SYNDROME PATIENTS RESIDING IN GERMANY
Lage MJ1, McCollam PL2, Bae JP2
1HealthMetrics Outcomes Research, LLC, Groton, CT, USA; 2Eli Lilly and Company, Indianapolis, IN, USA
OBJECTIVES: The European Society of Cardiology consensus treatment guidelines in 2002 support use of clopidogrel in many ACS patients for secondary prevention of cardiac events. This study is to examine clopidogrel patterns of use in acute coronary syndrome (ACS) patients in Germany. METHODS: The data source was the IMS Health, Disease Analyzer Medipius-German database, containing approximately 4.2 million de-identified patient records from approximately 1000 participating practices. The analysis period was January 1, 2001—September 30, 2004. The index ACS event was identified using ICD-10 codes for unstable angina or acute myocardial infarction. Patients were included if they had ≥3 months of data before and after an index ACS event and ≥1 prescription for clopidogrel after the event. RESULTS: Of the 28,688 patients included in the ACS cohort, 748 had at least one clopidogrel prescription (2.6%) and met inclusion criteria. Mean age was 67.5 years; 68% were male. The mean number of recorded comorbidities was 7.4. High cholesterol, hypertension, angina, ischemic heart disease, and diabetes were most common. The recorded mean length of clopidogrel therapy was 41 days. 74% of patients stopped therapy, defined as not on clopidogrel 28-days prior to end of follow-up. A gap in therapy, defined as late refills >14 days apart, was seen in 89%. Concomitant cardiovascular drug therapies included: calcium channel blocker (20.3%), beta-blocker (69.1%) and statin (64.7%). CONCLUSION: This descriptive study suggests clopidogrel is underutilized in ACS patients and long-term adherence to therapy was poor as demonstrated by stoppages or gaps in therapy.

OBJECTIVE: The need for treatment of cardiac disease in women can go unrecognised and access to appropriate health care can be limited. We evaluated the effect of gender on changes in long-term health-related quality of life (HRQoL) after coronary stent implantation (CSI) in conventional treatment of coronary artery disease (CAD). METHOD: In this prospective comparative multi-centre cohort study in Germany, patients with CAD undergoing coronary angioplasty were electively treated with stents. Standardised questionnaires were completed by patients at baseline, 3, 6, 12, and 18 months following angioplasty and documented patient health-related (SF-36) and disease-specific (MacNew heart disease questionnaire) quality of life, as well as clinical outcomes. RESULTS: From April until August 2004, 103 women (16%, mean age 66, b11) und 546 men (mean age 64, b10) were treated with CSI. There were no significant differences in socio-demographic factors, cardiovascular risk factors and severity of CAD. At baseline, all aspects of HRQoL evaluated by SF-36 and MacNew were significantly poorer in women than in men (p = 0.004). Three months following stent implantation, the difference in improvement in the SF-36 aspects of general health (p = 0.005), role emotional (p = 0.034) and the mental summary score (p = 0.027) was significantly greater in women than in men, although their actual HRQoL remained significantly lower in most aspects. After 6 months, the difference in improvement in women was significantly greater to baseline in the aspect of role emotional than men (p = 0.019). Gender differences in improvement were not demonstrated in the follow-up MacNew questionnaires. CONCLUSIONS: In comparison to men, baseline HRQoL in women may be lower before receiving CSI treatment. However, three and six months following implantation of a coronary stent, the difference in improvement in many aspects of HRQoL was greater in women than in men. Women may have a wider range of potential improvement after coronary stent implantation than men.

HEALTH RELATED QUALITY OF LIFE IN PATIENTS WITH CORONARY HEART DISEASE: A STUDY USING EQ-5D QUESTIONNAIRE
De Portu S1, Monzini M2, Galietti M3, Mantovani LG4
1University of Naples, Naples, Italy; 2Center of Pharmacoeconomics, Milan, Italy; 3University of Milan, Milan, Italy
OBJECTIVES: Coronary heart disease (CHD) is nowadays the most frequent cause of mortality and morbidity in industrialized countries. In Europe it accounts for around two million deaths
portal sociodemographic differences. RESULTS: We analyzed two groups of 98 subjects per group. The mean age was 64.7 (SD 8.6) years, (69.4%) were male. More problems were reported in cases than in controls in the mobility dimension, usual activities, and self care and anxiety/depression dimensions. These differences proved statistically significant. Whereas in pain/discomfort domain there was no significant difference between the two groups. Mean values of the visual analogue scale assessing global health status indicated by case and control were 68.1 and 66.9, respectively (P = 0.005). CONCLUSION: The study, comparing subjects of the same age and sex with and without CHD, suggests that the presence of CHD is associated with higher problems in HR.

PORTUGUESE ACTIVE POPULATION HEALTH RELATED QUALITY OF LIFE RESULTS USING THE SF-6D

Ferreira LN1, Ferreira PL2

1University of Algarve, Faro, Algarve, Portugal; 2University of Coimbra, Coimbra, Coimbra, Portugal

OBJECTIVES: This study aims to describe the health related quality of life (HRQOL) of the Portuguese population and investigates sociodemographic differences. METHODS: Subjects randomly selected from the Portuguese active population (n = 2459) were assessed using the SF-36, a generic measure of HRQOL, which was converted into the preference-based SF-6D, following the Brazier algorithm. Although the sample was randomly selected, it differed slightly from the whole population. In order to correct this, post-stratified statically techniques were used to weight the initial results by gender and age, according to the population values. RESULTS: Mean global utility SF-6D scores were 0.70, and ranged from 0.73 (18–24 years) to 0.63 (55–64 years). The mean utility scores were 0.17 lower in the lower educational level than in the higher educational level (p < 0.000). Women, people living in rural areas and the elderly reported lower levels of utility scores. Nonparametric tests showed that health utility values were significantly related to employment (p < 0.000): the unskilled manual workers (0.68) reported lower utility values than the non-manual workers (0.74). For different diseases mean utility scores ranged from 0.66 (hepatitis) to 0.56 (stroke). This study was able to achieve normative data by age and gender for the SF-6D. Using QALYs as outcome measures, the difference between unskilled manual workers and non-manual workers would be equivalent to a difference of 4902€ in annual income. In this line of thinking, the difference between lower educational level and higher educational level would be equivalent to a difference of 13,889€ in annual income. CONCLUSION: We conclude that the SF-6D is an efficient tool for measuring the HRQOL in the community, so that different population groups can be compared. The preference-based utility measure used seems to adequately discriminate across different sociodemographic differences, showing that the HRQOL varies greatly between sociodemographic groups.
