surgery. However, with newer DES and better adjunctive imaging techniques (IVUS, OCT), ULMCA angioplasty & stenting has become an attractive alternative in certain situations. Here, we present our single-unit experience in LMCA stenting over the last 7 years.

**Methods**: We performed 12 cases of ULMCA stenting over the last 7 years. There were 8 male and 4 female in the age group of 34 – 82 years. The etiology was atherosclerosis in 11 and aortoarteritis in one. 7 cases were emergency procedures (primary PCI in acute MI), of which 5 were in cardiogenic shock. LAD occlusion involving distal LMCA bifurcation was seen in 4, LAD occlusion with mid shaft independent stenosis in 2 and spontaneous dissection of LMCA involving LAD & LCX was seen in 1 postpartum lady. 5cases were elective PCIs: all were approved by heart-team with high surgical risk in 3 and patient choice in 2. Two had ostial stenosis, 2 had mid-shaft stenosis and 1 had diffuse LMCA stenosis. IABP insertion was done in all emergency cases and in 2 elective cases with severe LV dysfunction.

**Results**: Transfemoral access was used in 11. Transradial access was done in 1 with additional transfemoral access during the procedure for SKS stenting using a novel simultaneous kissing guide technique for LMCA bifurcation stenting with large LMCA and equal sized smaller LAD & LCX. 6 & 7F guide catheters were used in all. Adjunctive techniques included catheter thrombus aspiration in 5 emergency cases, Flextome cutting balloon in 1 elective case. Adjunctive IVUS imaging was used in 2 elective cases and OCT in 1, and in none of the emergency cases. Single stent strategy was used in 10 (including crossover stenting), 1 SKS and 1 TAP. DES were used in all but 4 cases. Pharmacology was dual (8) or triple (4) antiplatelet therapy. The procedural success was 100%. In-hospital mortality occurred in 1 emergency case with cardiogenic shock; no mortality at 30-days in the rest. LV function had improved in all primary cases.

On follow up, routine coronary angiography was done in 4 patients, CT coronary angiography in 4, while 2 patients who were clinically stable opted out of repeat coronary angiography. **Conclusion**: Unprotected LMCA stenting is increasingly being undertaken both in emergency situations and in selected elective cases. The results are encouraging but challenging problems are encountered in emergency cases (will be discussed).

## Differential pattern of commissural split and it's impact on mitral valve orifice following PTMC

S. Kumaran, M.S. Ravi, K. Meenakshi, D. Muthukumar,

N. Swaminathan, G. Ravishankar, G. Justin Paul, G. Manohar, S. Murugan, S. Vengatesan

Madras Medical College, Chennai, India

**Background**: Aim is to analyse the pattern of commissural split by 2D echo, in severe Rheumatic mitral stenosis (Rh MS) by PTMC. We have studied which commissure splits and what factors decide to cause maximal lumen gain without significant mitral regurgitation.

Methods: It is a single centre prospective analytical study (April -June 2014), on 35 patients aged between 15 to 40 yrs. Patients with Padial score < 10 were included. Padial preferred over Wilkinson's score, since it takes into consideration individual commissures. PTMC procedure was done by standard protocol with Accura balloon. All the patients underwent TTE by Esoate My Lab 30 Gold machine to analyse mitral commissures. Severe Rh MS defined as MV area of less than 1.0 sq cm. Success of the procedure was defined as increasing in valve area by 50%, with at least 1+ increase in mitral regurgitation (MR).Study groups have undergone PTMC by Accura Balloon, size ranging from 24 - 26mm.

**Results**: Out of 35 patients 85.5% were females and 14.5% males. Free medial commissures in 15 pts with mean Padial echo score of 7.5(6.5 to 8.5) had split through same commissure. Free lateral commissure in 11 pts with mean Padial echo score of 8.5 (7.5 to 9.5) had split through same commissure post procedurally. 9 pts had both commissures fused pre procedurally, in whom 3 developed medial commissure split, 2 pts developed lateral commissure split. Remaining 4 pts developed both commissure split on second dilatation. Bi commissural split occurred when the balloon was dilated to 26 mm in 3 pts. One patient with medial commissures free developed both commissure split on 26 mm dilatation for the second time. Medial commissure split cause gain in MV area by 35%, bi commissural split 37% and the lateral commissure split 15%.

**Conclusion**: Commissural split following PTMC occur in differential and unpredictable pattern. Medial commissure split more common than lateral followed by bi commissural. The gain in MVO is found maximum with medial commissure than lateral. Balloon sizing and the number of inflations predominantly decide the outcome. Current PTMC techniques doesn't allow targeted commissural split. Further refinement of PTMC procedures may be desirable.

## Clinical Profile and outcomes of overlapping v/s single long stent in long coronary lesions – The Trivandrum Long Stent (TRILO) Study"

Anil Balachandran, Kiran Gopinath, Prabha Nini Gupta, A. George Koshy, Sunitha Viswanathan

Government Medical College, Thiruvananthapuram, India

**Background**: Long coronary lesions represent a difficult lesion subset both from technical standpoint as well as clinical outcomes. In the current treatment of long coronary stenoses, conclusive data are lacking regarding the efficacy of multiple overlapping stents vs. single long stents. The research question of the study was to investigate whether overlapping long stents are associated with a higher number of adverse clinical events as compared to long stents of comparable length.

**Methods**: Retrospective study involving registry data 455 consecutive patients admitted for angioplasty over a period of one year. The patients were divided into two categories- with overlapping stents with stented length more than or equal to 40mm in a single vessel and with a single long stent of length more than or equal to 40mm. The baseline characteristics, in-hospital events and angioplasty details were analyzed. Outcomes at 6 months were compared using the Chi square test.

**Results**: During the study period 455 patients underwent stent implantation with a stented length more than 40mm. There were 273 patients in the overlapping stent group and 182 patients in the long stent group. There was high prevalence of conventional coronary risk factors like diabetes and systemic hypertension in study groups. A high proportion of the study cohort had a history of ACS (Past and present) reflecting the high risk nature of the study cohort (67.9% v/s 74.5%)Femoral was the preferred access route in both groups (72% v/s 52%) MACE events were comparable between two groups at the end of 6 months. Stent thrombosis
