#### Abstract

Let X be a finite dimensional compact metrizable space. We study a technique which employs semiprojectivity as a tool to produce approximations of C(X)-algebras by C(X)-subalgebras with controlled complexity. The following applications are given. All unital separable continuous fields of  $C^*$ -algebras over X with fibers isomorphic to a fixed Cuntz algebra  $\mathcal{O}_n$ ,  $n \in \{2, 3, \dots, \infty\}$ , are locally trivial. They are trivial if n = 2 or  $n = \infty$ . For  $n \geqslant 3$  finite, such a field is trivial if and only if  $(n-1)[1_A] = 0$  in  $K_0(A)$ , where A is the  $C^*$ -algebra of continuous sections of the field. We give a complete list of the Kirchberg algebras D satisfying the UCT and having finitely generated K-theory groups for which every unital separable continuous field over X with fibers isomorphic to D is automatically locally trivial or trivial. In a more general context, we show that a separable unital continuous field over X with fibers isomorphic to a KK-semiprojective Kirchberg  $C^*$ -algebra is trivial if and only if it satisfies a K-theoretical Fell type condition.

#### 1. Introduction

The Gelfand–Naimark characterization of commutative  $C^*$ -algebras has suggested the problem of representing noncommutative  $C^*$ -algebra as sections of bundles. By a result of Fell [15], if the primitive spectrum X of a separable  $C^*$ -algebra A is Hausdorff, then A is isomorphic to the  $C^*$ -algebra of continuous sections vanishing at infinity of a continuous field of simple  $C^*$ -algebras over X. In particular A is a continuous C(X)-algebra in the sense of Kasparov [18]. This description is very satisfactory, since as explained in [4], the continuous fields of  $C^*$ -algebras are in natural correspondence with the bundles of  $C^*$ -algebras in the sense of topology. Nevertheless, only a tiny fraction of the continuous fields of  $C^*$ -algebras corresponds to locally trivial bundles.

In this paper we prove automatic and conditional local/global trivialization results for continuous fields of Kirchberg algebras. By a Kirchberg algebra we mean a purely infinite simple nuclear separable C\*-algebra [29]. Notable examples include the simple Cuntz–Krieger algebras [8]. The following theorem illustrates our results.

**Theorem 1.1.** A separable unital C(X)-algebra A over a finite dimensional compact Hausdorff space X all of whose fibers are isomorphic to the same Cuntz algebra  $\mathcal{O}_n$ ,  $n \in \{2, 3, ..., \infty\}$ , is locally trivial. If n = 2 or  $n = \infty$ , then  $A \cong C(X) \otimes \mathcal{O}_n$ . If  $3 \leq n < \infty$ , then A is isomorphic to  $C(X) \otimes \mathcal{O}_n$  if and only if  $(n - 1)[1_A] = 0$  in  $K_0(A)$ .

The case X = [0, 1] of Theorem 1.1 was proved in a joint paper with G. Elliott [10]. We parametrize the homotopy classes

$$[X, \operatorname{Aut}(\mathcal{O}_n)] \cong \begin{cases} K_1(C(X) \otimes \mathcal{O}_n) & \text{if } 3 \leq n < \infty, \\ \{*\} & \text{if } n = 2, \infty \end{cases}$$

(see Theorem 7.4), and hence classify the unital separable C(SX)-algebras A with fiber  $\mathcal{O}_n$  over the suspension SX of a finite dimensional metrizable Hausdorff space X.

To put our results in perspective, let us recall that none of the general basic properties of a continuous field implies any kind of local triviality. An example of a continuous field of Kirchberg algebras over [0, 1] which is not locally trivial at any point even though all of its fibers are mutually isomorphic is exhibited in [10, Ex. 8.4]. Examples of nonexact continuous fields with similar properties were found by S. Wassermann [37].

A separable C\*-algebra D is KK-semiprojective if the functor KK(D, -) is continuous, see Section 3. The class of KK-semiprojective C\*-algebras includes the nuclear semiprojective C\*-algebras and also the C\*-algebras which satisfy the Universal Coefficient Theorem in KK-theory (abbreviated UCT [31]) and whose K-theory groups are finitely generated. It is very interesting

that the *only obstruction* to local or global triviality for a continuous field of Kirchberg algebras is of purely K-theoretical nature.

**Theorem 1.2.** Let A be a separable  $C^*$ -algebra whose primitive spectrum X is compact Hausdorff and of finite dimension. Suppose that each primitive quotient A(x) of A is nuclear, purely infinite and stable. Then A is isomorphic to  $C(X) \otimes D$  for some KK-semiprojective stable Kirchberg algebra D if and only if there is  $\sigma \in KK(D,A)$  such that  $\sigma_x \in KK(D,A(x))^{-1}$  for all  $x \in X$ . For any such  $\sigma$  there is an isomorphism of C(X)-algebras  $\Phi : C(X) \otimes D \to A$  such that  $KK(\Phi|_D) = \sigma$ .

We have an entirely similar result covering the unital case: Theorem 7.3. The required existence of  $\sigma$  is a KK-theoretical analog of the classical condition of Fell that appears in the trivialization theorem of Dixmier and Douady [12] of continuous fields with fibers isomorphic to the compact operators. An important feature of our condition is that it is a priori much weaker than the condition that A is  $KK_{C(X)}$ -equivalent to  $C(X) \otimes D$ . In particular, we do not need to worry at all about the potentially hard issue of constructing elements in  $KK_{C(X)}(A, C(X) \otimes D)$ . To illustrate this point, let us note that it is almost trivial to verify that the local existence of  $\sigma$  is automatic for unital C(X)-algebras with fiber  $\mathcal{O}_n$  and hence to derive Theorem 1.1. A C\*-algebra D has the *automatic local triviality property* if any separable C(X)-algebra over a finite dimensional compact Hausdorff space X all of whose fibers are isomorphic to D is locally trivial. A unital C\*-algebra over a finite dimensional compact Hausdorff space X all of whose fibers are isomorphic to D is locally trivial. The *automatic triviality property* is defined similarly.

**Theorem 1.3** (Automatic triviality). A separable continuous C(X)-algebra over a finite dimensional compact Hausdorff space X all of whose fibers are isomorphic to  $\mathcal{O}_2 \otimes \mathcal{K}$  is isomorphic to  $C(X) \otimes \mathcal{O}_2 \otimes \mathcal{K}$ . The  $C^*$ -algebra  $\mathcal{O}_2 \otimes \mathcal{K}$  is the only Kirchberg algebra satisfying the automatic local triviality property and hence the automatic triviality property.

**Theorem 1.4** (Automatic local triviality in the unital sense). A unital KK-semiprojective Kirchberg algebra D has the automatic local triviality property in the unital sense if and only if all unital \*-endomorphisms of D are KK-equivalences. In that case, if A is a separable unital C(X)-algebra over a finite dimensional compact Hausdorff space X all of whose fibers are isomorphic to D, then  $A \cong C(X) \otimes D$  if and only if there is  $\sigma \in KK(D, A)$  such that the induced homomorphism  $K_0(\sigma) : K_0(D) \to K_0(A)$  maps  $[1_D]$  to  $[1_A]$ .

It is natural to ask if there are other unital Kirchberg algebras besides the Cuntz algebras which have the automatic local triviality property in the unital sense. Consider the following list  $\mathcal{G}$  of pointed abelian groups:

- (a)  $(\{0\}, 0)$ ;
- (b)  $(\mathbb{Z}, k)$  with k > 0;
- (c)  $(\mathbb{Z}/p^{e_1}\oplus\cdots\oplus\mathbb{Z}/p^{e_n},\,p^{s_1}\oplus\cdots\oplus p^{s_n})$  where p is a prime,  $n\geqslant 1,\,0\leqslant s_i< e_i$  for  $1\leqslant i\leqslant n$  and  $0< s_{i+1}-s_i< e_{i+1}-e_i$  for  $1\leqslant i< n$ . If n=1 the latter condition is vacuous. Note that if the integers  $1\leqslant e_1\leqslant\cdots\leqslant e_n$  are given then there exists integers  $s_1,\ldots,s_n$  satisfying the conditions above if and only if  $e_{i+1}-e_i\geqslant 2$  for each  $1\leqslant i\leqslant n$ . If that is the case one can choose  $s_i=i-1$  for  $1\leqslant i\leqslant n$ .

- (d)  $(G(p_1) \oplus \cdots \oplus G(p_m), g_1 \oplus \cdots \oplus g_m)$  where  $p_1, \ldots, p_m$  are distinct primes and each  $(G(p_i), g_i)$  is a pointed group as in (c).
- (e)  $(\mathbb{Z} \oplus G(p_1) \oplus \cdots \oplus G(p_m), k \oplus g_1 \oplus \cdots \oplus g_m)$  where  $(G(p_j), g_j)$  are as in (d). Moreover we require that k > 0 is divisible by  $p_1^{s_{n(1)}+1} \cdots p_m^{s_{n(m)}+1}$  where  $s_{n(j)}$  is defined as in (c) corresponding to the prime  $p_j$ .

**Theorem 1.5** (Automatic local triviality in the unital sense – the UCT case). Let D be a unital Kirchberg algebra which satisfies the UCT and has finitely generated K-theory groups. (i) D has the automatic triviality property in the unital sense if and only if D is isomorphic to either  $\mathcal{O}_2$  or  $\mathcal{O}_\infty$ . (ii) D has the automatic local triviality property in the unital sense if and only if  $K_1(D) = 0$  and  $(K_0(D), [1_D])$  is isomorphic to one of the pointed groups from the list  $\mathcal{G}$ . (iii) If D is as in (ii), then a separable unital C(X)-algebra A over a finite dimensional compact Hausdorff space X all of whose fibers are isomorphic to D is trivial if and only if there exists a homomorphism of groups  $K_0(D) \to K_0(A)$  which maps  $[1_D]$  to  $[1_A]$ .

We use semiprojectivity (in various flavors) to approximate and represent continuous C(X)-algebras as inductive limits of fibered products of n locally trivial C(X)-subalgebras where  $n \le \dim(X) < \infty$ . This clarifies the local structure of many C(X)-algebras (see Theorem 5.2) and gives a new understanding of the K-theory of separable continuous C(X)-algebras with arbitrary nuclear fibers.

A remarkable isomorphism result for separable nuclear strongly purely infinite stable C\*-algebras was announced (with an outline of the proof) by Kirchberg in [20]: two such C\*-algebras A and B with the same primitive spectrum X are isomorphic if and only if they are  $KK_{C(X)}$ -equivalent. This is always the case after tensoring with  $\mathcal{O}_2$ . However the problem of recognizing when A and B are  $KK_{C(X)}$ -equivalent is open even for very simple spaces X such as the unit interval or non-Hausdorff spaces with more than two points.

The proof of Theorem 4.6 (one of our main results) generalizes and refines a technique that was pioneered for fields over zero dimensional spaces in joint work with Pasnicu [11] and for fields over an interval in joint work with G. Elliott [10]. We shall rely heavily on the classification theorem (and related results) of Kirchberg [19] and Phillips [28], and on the work on nonsimple nuclear purely infinite C\*-algebras of Blanchard and Kirchberg [5,4] and Kirchberg and Rørdam [21,22].

The author is grateful to E. Blanchard, L.G. Brown and N.C. Phillips for useful discussions and comments.

### 2. C(X)-algebras

Let X be a locally compact Hausdorff space. A C(X)-algebra is a  $C^*$ -algebra A endowed with a \*-homomorphism  $\theta$  from  $C_0(X)$  to the center ZM(A) of the multiplier algebra M(A) of A such that  $C_0(X)A$  is dense in A; see [18,3]. We write fa rather than  $\theta(f)a$  for  $f \in C_0(X)$  and  $a \in A$ . If  $Y \subseteq X$  is a closed set, we let  $C_0(X,Y)$  denote the ideal of  $C_0(X)$  consisting of functions vanishing on Y. Then  $C_0(X,Y)A$  is a closed two-sided ideal of A (by Cohen factorization). The quotient of A by this ideal is a C(X)-algebra denoted by A(Y) and is called the restriction of A = A(X) to Y. The quotient map is denoted by  $\pi_Y : A(X) \to A(Y)$ . If Z is a closed subset of X we have a natural restriction map  $X_0$  and  $X_0$  and  $X_0$  and  $X_0$  and  $X_0$  are  $X_0$  is called the fiber of X at X. The image  $X_0$  for X is denoted by X is denoted by X and X and X is called the fiber of X at X. The image X is denoted by X is denoted by X and X and X is called the fiber of X at X. The image X is denoted by X is called the fiber of X at X. The image X is denoted by X is denoted by

 $\eta:A\to B$  induces a morphism  $\eta_Y:A(Y)\to B(Y)$ . If  $A(x)\neq 0$  for x in a dense subset of X, then  $\theta$  is injective. If X is compact, then  $\theta(1)=1_{M(A)}$ . Let A be a C\*-algebra,  $a\in A$  and  $\mathcal{F},\mathcal{G}\subseteq A$ . Throughout the paper we will assume that X is a compact Hausdorff space unless stated otherwise. If  $\varepsilon>0$ , we write  $a\in_{\varepsilon}\mathcal{F}$  if there is  $b\in\mathcal{F}$  such that  $\|a-b\|<\varepsilon$ . Similarly, we write  $\mathcal{F}\subset_{\varepsilon}\mathcal{G}$  if  $a\in_{\varepsilon}\mathcal{G}$  for every  $a\in\mathcal{F}$ . The following lemma collects some basic properties of C(X)-algebras.

**Lemma 2.1.** Let A be a C(X)-algebra and let  $B \subset A$  be a C(X)-subalgebra. Let  $a \in A$  and let Y be a closed subset of X.

- (i) The map  $x \mapsto ||a(x)||$  is upper semicontinuous.
- (ii)  $\|\pi_Y(a)\| = \max\{\|\pi_X(a)\|: x \in Y\}.$
- (iii) If  $a(x) \in \pi_x(B)$  for all  $x \in X$ , then  $a \in B$ .
- (iv) If  $\delta > 0$  and  $a(x) \in_{\delta} \pi_x(B)$  for all  $x \in X$ , then  $a \in_{\delta} B$ .
- (v) The restriction of  $\pi_x : A \to A(x)$  to B induces an isomorphism  $B(x) \cong \pi_x(B)$  for all  $x \in X$ .

**Proof.** (i), (ii) are proved in [3] and (iii) follows from (iv). (iv): By assumption, for each  $x \in X$ , there is  $b_x \in B$  such that  $\|\pi_x(a-b_x)\| < \delta$ . Using (i) and (ii), we find a closed neighborhood  $U_x$  of x such that  $\|\pi_{U_x}(a-b_x)\| < \delta$ . Since X is compact, there is a finite subcover  $(U_{x_i})$ . Let  $(\alpha_i)$  be a partition of unity subordinated to this cover. Setting  $b = \sum_i \alpha_i b_{x_i} \in B$ , one checks immediately that  $\|\pi_x(a-b)\| \le \sum_i \alpha_i(x) \|\pi_x(a-b_{x_i})\| < \delta$ , for all  $x \in X$ . Thus  $\|a-b\| < \delta$  by (ii). (v): If  $\iota: B \hookrightarrow A$  is the inclusion map, then  $\pi_x(B)$  coincides with the image of  $\iota_x: B/C(X,x)B \to A/C(X,x)A$ . Thus it suffices to check that  $\iota_x$  is injective. If  $\iota_x(b+C(X,x)B) = \pi_x(b) = 0$  for some  $b \in B$ , then b = fa for some  $f \in C(X,x)$  and some  $a \in A$ . If  $(f_\lambda)$  is an approximate unit of C(X,x), then  $b = \lim_{\lambda} f_{\lambda} fa = \lim_{\lambda} f_{\lambda} b$  and hence  $b \in C(X,x)B$ .  $\square$ 

A C(X)-algebra such that the map  $x \mapsto ||a(x)||$  is continuous for all  $a \in A$  is called a *continuous* C(X)-algebra or a C\*-bundle [3,23,4]. A C\*-algebra A is a continuous C(X)-algebra if and only if A is the C\*-algebra of continuous sections of a continuous field of C\*-algebras over X in the sense of [12, Def. 10.3.1] (see [3,4,27]).

**Lemma 2.2.** Let A be a separable continuous C(X)-algebra over a locally compact Hausdorff space X. If all the fibers of A are nonzero, then X has a countable basis of open sets. Thus the compact subspaces of X are metrizable.

**Proof.** Since *A* is separable, its primitive spectrum Prim(A) has a countable basis of open sets by [12, 3.3.4]. The continuous map  $\eta : Prim(A) \to X$  (induced by  $\theta : C_0(X) \to ZM(A) \cong C_b(Prim(A))$ ) is open since the C(X)-algebra *A* is continuous and surjective since  $A(x) \neq 0$  for all  $x \in X$  (see [4, p. 388] and [27, Prop. 2.1, Thm. 2.3]).  $\square$ 

**Lemma 2.3.** Let X be a compact metrizable space. A C(X)-algebra A all of whose fibers are nonzero and simple is continuous if and only if there is  $e \in A$  such that  $||e(x)|| \ge 1$  for all  $x \in X$ .

**Proof.** By Lemma 2.1(i) it suffices to prove that  $\liminf_{n\to\infty} \|a(x_n)\| \ge \|a(x_0)\|$  for any  $a \in A$  and any sequence  $(x_n)$  converging to  $x_0$  in X. Set  $D = A(x_0)$  and let e be as in the statement. Let  $\psi: D \to A$  be a set-theoretical lifting of  $\mathrm{id}_D$  such that  $\|\psi(d)\| = \|d\|$  for all  $d \in D$ . Then  $\lim_{n\to\infty} \|\pi_{x_n}\psi(a(x_0)) - a(x_n)\| = 0$  for all  $a \in A$ , by Lemma 2.1(i). By applying this

to e, since  $\|e(x_n)\| \ge 1$ , we see that  $\liminf_{n\to\infty} \|\pi_{x_n}\psi(e(x_0))\| \ge 1$ . Since D is a simple C\*-algebra, if  $\varphi_n: D \to B_n$  is a sequence of contractive maps such that  $\lim_{n\to\infty} \|\varphi_n(\lambda c+d) - \lambda \varphi_n(c) - \varphi_n(d)\| = 0$ ,  $\lim_{n\to\infty} \|\varphi_n(cd) - \varphi_n(c)\varphi_n(d)\| = 0$ ,  $\lim_{n\to\infty} \|\varphi_n(c^*) - \varphi_n(c)^*\| = 0$ , for all  $c, d \in D$ ,  $\lambda \in \mathbb{C}$ , and  $\liminf_{n\to\infty} \|\varphi_n(c)\| > 0$  for some  $c \in D$ , then  $\lim_{n\to\infty} \|\varphi_n(c)\| = \|c\|$  for all  $c \in D$ . In particular this observation applies to  $\varphi_n = \pi_{x_n} \psi$  by Lemma 2.1(i). Therefore

$$\liminf_{n \to \infty} \|a(x_n)\| \ge \liminf_{n \to \infty} (\|\pi_{x_n} \psi(a(x_0))\| - \|\pi_{x_n} \psi(a(x_0)) - a(x_n)\|) = \|a(x_0)\|.$$

Conversely, if A is continuous, take e to be a large multiple of some full element of A.  $\Box$ 

Let  $\eta: B \to A$  and  $\psi: E \to A$  be \*-homomorphisms. The *pullback* of these maps is

$$B \oplus_{\eta,\psi} E = \{(b,e) \in B \oplus E \colon \eta(b) = \psi(e)\}.$$

We are going to use pullbacks in the context of C(X)-algebras. Let X be a compact space and let Y, Z be closed subsets of X such that  $X = Y \cup Z$ . The following result is proved in [12, Prop. 10.1.13] for continuous C(X)-algebras.

**Lemma 2.4.** If A is a C(X)-algebra, then A is isomorphic to  $A(Y) \oplus_{\pi,\pi} A(Z)$ , the pullback of the restriction maps  $\pi_{Y \cap Z}^Y : A(Y) \to A(Y \cap Z)$  and  $\pi_{Y \cap Z}^Z : A(Z) \to A(Y \cap Z)$ .

**Proof.** By the universal property of pullbacks, the maps  $\pi_Y$  and  $\pi_Z$  induce a map  $\eta: A \to A(Y) \oplus_{\pi,\pi} A(Z)$ ,  $\eta(a) = (\pi_Y(a), \pi_Z(a))$ , which is injective by Lemma 2.1(ii). Thus it suffices to show that the range of  $\eta$  is dense. Let  $b, c \in A$  be such that  $\pi_{Y \cap Z}(b-c) = 0$  and let  $\varepsilon > 0$ . We shall find  $a \in A$  such that  $\|\eta(a) - (\pi_Y(b), \pi_Z(c))\| < \varepsilon$ . By Lemma 2.1(i), there is an open neighborhood V of  $Y \cap Z$  such that  $\|\pi_X(b-c)\| < \varepsilon$  for all  $x \in V$ . Let  $\{\lambda, \mu\}$  be a partition of unity on X subordinated to the open cover  $\{Y \cup V, Z \cup V\}$ . Then  $a = \lambda b + \mu c$  is an element of A which has the desired property.  $\square$ 

Let  $B \subset A(Y)$  and  $E \subset A(Z)$  be C(X)-subalgebras such that  $\pi^Z_{Y \cap Z}(E) \subseteq \pi^Y_{Y \cap Z}(B)$ . As an immediate consequence of Lemma 2.4 we see that the pullback  $B \oplus_{\pi^Z_{Y \cap Z}, \pi^Y_{Y \cap Z}} E$  is isomorphic to the C(X)-subalgebra  $B \oplus_{Y \cap Z} E$  of A defined as

$$B \oplus_{Y \cap Z} E = \{ a \in A \colon \pi_Y(a) \in B, \ \pi_Z(a) \in E \}.$$

**Lemma 2.5.** The fibers of  $B \oplus_{Y \cap Z} E$  are given by

$$\pi_{X}(B \oplus_{Y \cap Z} E) = \begin{cases} \pi_{X}(B), & \text{if } x \in X \setminus Z, \\ \pi_{X}(E), & \text{if } x \in Z, \end{cases}$$

and there is an exact sequence of C\*-algebras

$$0 \longrightarrow \left\{ b \in B \colon \pi_{Y \cap Z}(b) = 0 \right\} \longrightarrow B \oplus_{Y \cap Z} E \xrightarrow{\pi_Z} E \longrightarrow 0. \tag{1}$$

**Proof.** Let  $x \in X \setminus Z$ . The inclusion  $\pi_x(B \oplus_{Y \cap Z} E) \subset \pi_x(B)$  is obvious by definition. Given  $b \in B$ , let us choose  $f \in C(X)$  vanishing on Z and such that f(x) = 1. Then a = (fb, 0) is an element of A by Lemma 2.4. Moreover  $a \in B \oplus_{Y \cap Z} E$  and  $\pi_x(a) = \pi_x(b)$ . We have  $\pi_Z(B \oplus_{Y \cap Z} E) \subset E$ , by definition. Conversely, given  $e \in E$ , let us observe that  $\pi_{Y \cap Z}^Z(e) \in \pi_{Y \cap Z}^Y(B)$  (by assumption) and hence  $\pi_{Y \cap Z}^Z(e) = \pi_{Y \cap Z}^Y(b)$  for some  $b \in B$ . Then a = (b, e) is an element of A by Lemma 2.4 and  $\pi_Z(a) = e$ . This completes the proof for the first part of the lemma and also it shows that the map  $\pi_Z$  from the sequence (1) is surjective. Its kernel is identified using Lemma 2.1(iii).  $\square$ 

Let X, Y, Z and A be as above. Let  $\eta: B \hookrightarrow A(Y)$  be a C(Y)-linear \*-monomorphism and let  $\psi: E \hookrightarrow A(Z)$  be a C(Z)-linear \*-monomorphism. Assume that

$$\pi_{Y \cap Z}^{Z}(\psi(E)) \subseteq \pi_{Y \cap Z}^{Y}(\eta(B)). \tag{2}$$

This gives a map  $\gamma = \eta_{Y \cap Z}^{-1} \psi_{Y \cap Z} : E(Y \cap Z) \to B(Y \cap Z)$ . To simplify notation we let  $\pi$  stand for both  $\pi_{Y \cap Z}^{Y}$  and  $\pi_{Z \cap Z}^{Z}$  in the following lemma.

#### Lemma 2.6.

(a) There are isomorphisms of C(X)-algebras

$$B \oplus_{\pi,\gamma\pi} E \cong B \oplus_{\pi\eta,\pi\psi} E \cong \eta(B) \oplus_{Y\cap Z} \psi(E),$$

where the second isomorphism is given by the map  $\chi: B \oplus_{\pi\eta,\pi\psi} E \to A$  induced by the pair  $(\eta, \psi)$ . Its components  $\chi_x$  can be identified with  $\psi_x$  for  $x \in Z$  and with  $\eta_x$  for  $x \in X \setminus Z$ .

- (b) Condition (2) is equivalent to  $\psi(E) \subset \pi_Z(A \oplus_Y \eta(B))$ .
- (c) If  $\mathcal{F}$  is a finite subset of A such that  $\pi_Y(\mathcal{F}) \subset_{\varepsilon} \eta(B)$  and  $\pi_Z(\mathcal{F}) \subset_{\varepsilon} \psi(E)$ , then  $\mathcal{F} \subset_{\varepsilon} \eta(B) \oplus_{Y \cap Z} \psi(E) = \chi(B \oplus_{\pi \eta, \pi \psi} E)$ .

**Proof.** This is an immediate corollary of Lemmas 2.1, 2.4, 2.5. For illustration, let us verify (c). By assumption  $\pi_x(\mathcal{F}) \subset_{\varepsilon} \eta_x(B)$  for all  $x \in X \setminus Z$  and  $\pi_z(\mathcal{F}) \subset_{\varepsilon} \psi_z(E)$  for all  $z \in Z$ . We deduce from Lemma 2.5 that  $\pi_x(\mathcal{F}) \subset_{\varepsilon} \pi_x(\eta(B) \oplus_{Y \cap Z} \psi(E))$  for all  $x \in X$ . Therefore  $\mathcal{F} \subset_{\varepsilon} \eta(B) \oplus_{Y \cap Z} \psi(E)$  by Lemma 2.1(iv).  $\square$ 

**Definition 2.7.** Let  $\mathcal{C}$  be a class of C\*-algebras. A C(Z)-algebra E is called C-elementary if there is a finite partition of Z into closed subsets  $Z_1, \ldots, Z_r$   $(r \geqslant 1)$  and there exist C\*-algebras  $D_1, \ldots, D_r$  in  $\mathcal{C}$  such that  $E \cong \bigoplus_{i=1}^r C(Z_i) \otimes D_i$ . The notion of *category* of a C(X)-algebra with respect to a class  $\mathcal{C}$  is defined inductively: if A is  $\mathcal{C}$ -elementary then  $\operatorname{cat}_{\mathcal{C}}(A) = 0$ ;  $\operatorname{cat}_{\mathcal{C}}(A) \leqslant n$  if there are closed subsets Y and Z of X with  $X = Y \cup Z$  and there exist a C(Y)-algebra B such that  $\operatorname{cat}_{\mathcal{C}}(B) \leqslant n-1$ , a  $\mathcal{C}$ -elementary C(Z)-algebra E and a \*-monomorphism of  $C(Y \cap Z)$ -algebras  $Y: E(Y \cap Z) \to B(Y \cap Z)$  such that A is isomorphic to

$$B \oplus_{\pi, \gamma\pi} E = \{(b, d) \in B \oplus E \colon \pi_{Y \cap Z}^{Y}(b) = \gamma \pi_{Y \cap Z}^{Z}(d)\}.$$

By definition  $cat_{\mathcal{C}}(A) = n$  if n is the smallest number with the property that  $cat_{\mathcal{C}}(A) \leq n$ . If no such n exists, then  $cat_{\mathcal{C}}(A) = \infty$ .

**Definition 2.8.** Let C be a class of  $C^*$ -algebras and let A be a C(X)-algebra. An n-fibered C-monomorphism  $(\psi_0, \ldots, \psi_n)$  into A consists of (n+1) \*-monomorphisms of C(X)-algebras  $\psi_i : E_i \to A(Y_i)$ , where  $Y_0, \ldots, Y_n$  is a closed cover of X, each  $E_i$  is a C-elementary  $C(Y_i)$ -algebra and

$$\pi_{Y_i \cap Y_j}^{Y_i} \psi_i(E_i) \subseteq \pi_{Y_i \cap Y_j}^{Y_j} \psi_j(E_j), \quad \text{for all } i \leqslant j.$$
 (3)

Given an *n*-fibered morphism into *A* we have an associated *continuous* C(X)-algebra defined as the fibered product (or pullback) of the \*-monomorphisms  $\psi_i$ :

$$A(\psi_0, \dots, \psi_n) = \left\{ (d_0, \dots, d_n) : d_i \in E_i, \ \pi_{Y_i \cap Y_j}^{Y_i} \psi_i(d_i) = \pi_{Y_i \cap Y_j}^{Y_j} \psi_j(d_j) \text{ for all } i, j \right\}$$
 (4)

and an induced C(X)-monomorphism (defined by using Lemma 2.4)

$$\eta = \eta_{(\psi_0, \dots, \psi_n)} : A(\psi_0, \dots, \psi_n) \to A \subset \bigoplus_{i=0}^n A(Y_i),$$
$$\eta(d_0, \dots, d_n) = (\psi_0(d_0), \dots, \psi_n(d_n)).$$

There are natural coordinate maps  $p_i: A(\psi_0, \dots, \psi_n) \to E_i$ ,  $p_i(d_0, \dots, d_n) = d_i$ . Let us set  $X_k = Y_k \cup \dots \cup Y_n$ . Then  $(\psi_k, \dots, \psi_n)$  is an (n-k)-fibered  $\mathcal{C}$ -monomorphism into  $A(X_k)$ . Let  $\eta_k: A(X_k)(\psi_k, \dots, \psi_n) \to A(X_k)$  be the induced map and set  $B_k = A(X_k)(\psi_k, \dots, \psi_n)$ . Let us note that  $B_0 = A(\psi_0, \dots, \psi_n)$  and that there are natural  $C(X_{k-1})$ -isomorphisms

$$B_{k-1} \cong B_k \oplus_{\pi \eta_k, \pi \psi_{k-1}} E_{k-1} \cong B_k \oplus_{\pi, \gamma_k \pi} E_{k-1}, \tag{5}$$

where  $\pi$  stands for  $\pi_{X_k \cap Y_{k-1}}$  and  $\gamma_k : E_{k-1}(X_k \cap Y_{k-1}) \to B_k(X_k \cap Y_{k-1})$  is defined by  $(\gamma_k)_x = (\eta_k)_x^{-1}(\psi_{k-1})_x$ , for all  $x \in X_k \cap Y_{k-1}$ . In particular, this decomposition shows that  $\operatorname{cat}_{\mathcal{C}}(A(\psi_0, \dots, \psi_n)) \leq n$ .

**Lemma 2.9.** Suppose that the class C from Definition 2.7 consists of stable Kirchberg algebras. If A is a C(X)-algebra over a compact metrizable space X such that  $cat_C(A) < \infty$ , then A contains a full properly infinite projection and  $A \cong A \otimes \mathcal{O}_{\infty} \otimes \mathcal{K}$ .

**Proof.** We prove this by induction on  $n = \operatorname{cat}_{\mathcal{C}}(A)$ . The case n = 0 is immediate since  $D \cong D \otimes \mathcal{O}_{\infty}$  for any Kirchberg algebra D [19]. Let  $A = B \oplus_{\pi, \gamma\pi} E$  where B, E and  $\gamma$  are as in Definition 2.7 with  $\operatorname{cat}_{\mathcal{C}}(B) = n - 1$  and  $\operatorname{cat}_{\mathcal{C}}(E) = 0$ . Let us consider the exact sequence  $0 \to J \to A \to E \to 0$ , where  $J = \{b \in B \colon \pi_{Y \cap Z}(b) = 0\}$ . Since J is an ideal of  $B \cong B \otimes \mathcal{O}_{\infty} \otimes \mathcal{K}$ , J absorbs  $\mathcal{O}_{\infty} \otimes \mathcal{K}$  by [22, Prop. 8.5]. Since both E and J are stable and purely infinite, it follows that A is stable by [30, Prop. 6.12] and purely infinite by [22, Prop. 3.5]. Since A has Hausdorff primitive spectrum, A is strongly purely infinite by [5, Thm. 5.8]. It follows that  $A \cong A \otimes \mathcal{O}_{\infty}$  by [22, Thm. 9.1]. Finally A contains a full properly infinite projection since there is a full embedding of  $\mathcal{O}_2$  into A by [5, Prop. 5.6].  $\square$ 

## 3. Semiprojectivity

In this section we study the notion of *KK*-semiprojectivity. The main result is Theorem 3.12. Let A and B be C\*-algebras. Two \*-homomorphisms  $\varphi$ ,  $\psi$ :  $A \to B$  are approximately unitarily equivalent, written  $\varphi \approx_u \psi$ , if there is a sequence of unitaries  $(u_n)$  in the C\*-algebra  $B^+ = B + \mathbb{C}1$  obtained by adjoining a unit to B, such that  $\lim_{n\to\infty} \|u_n\varphi(a)u_n^* - \psi(a)\| = 0$  for all  $a \in A$ . We say that  $\varphi$  and  $\psi$  are asymptotically unitarily equivalent, written  $\varphi \approx_{uh} \psi$ , if there is a norm continuous unitary valued map  $t \to u_t \in B^+$ ,  $t \in [0, 1)$ , such that  $\lim_{t\to 1} \|u_t\varphi(a)u_t^* - \psi(a)\| = 0$  for all  $a \in A$ . a \*-homomorphism  $\varphi$ :  $D \to A$  is full if  $\varphi(d)$  is not contained in any proper two-sided closed ideal of A if  $d \in D$  is nonzero.

We shall use several times Kirchberg's Theorem [29, Thm. 8.3.3] and the following theorem of Phillips [28].

**Theorem 3.1.** Let A and B be separable  $C^*$ -algebras such that A is simple and nuclear,  $B \cong B \otimes \mathcal{O}_{\infty}$ , and there exist full projections  $p \in A$  and  $q \in B$ . For any  $\sigma \in KK(A, B)$  there is a full \*-homomorphism  $\varphi : A \to B$  such that  $KK(\varphi) = \sigma$ . If  $K_0(\sigma)[p] = [q]$  then we may arrange that  $\varphi(p) = q$ . If  $\psi : A \to B$  is another \*-homomorphism such that  $KK(\psi) = KK(\varphi)$  and  $\psi(p) = q$ , then  $\varphi \approx_{uh} \psi$  via a path of unitaries  $t \mapsto u_t \in U(qBq)$ .

Theorem 3.1 does not appear in this form in [28] but it is an immediate consequence of [28, Thm. 4.1.1]. Since  $pAp \otimes \mathcal{K} \cong A \otimes \mathcal{K}$  and  $qBq \otimes \mathcal{K} \cong B \otimes \mathcal{K}$  by [6], and  $qBq \otimes \mathcal{O}_{\infty} \cong qBq$  by [22, Prop. 8.5], it suffices to discuss the case when p and q are the units of A and B. If  $\sigma$  is given, [28, Thm. 4.1.1] yields a full \*-homomorphism  $\varphi: A \to B \otimes \mathcal{K}$  such that  $KK(\varphi) = \sigma$ . Let  $e \in \mathcal{K}$  be a rank-one projection and suppose that  $[\varphi(1_A)] = [1_B \otimes e]$  in  $K_0(B)$ . Since both  $\varphi(1_A)$  and  $1_B \otimes e$  are full projections and  $B \cong B \otimes \mathcal{O}_{\infty}$ , it follows by [28, Lemma 2.1.8] that  $u\varphi(1_A)u^* = 1_B \otimes e$  for some unitary in  $(B \otimes \mathcal{K})^+$ . Replacing  $\varphi$  by  $u\varphi u^*$  we can arrange that  $KK(\varphi) = \sigma$  and  $\varphi$  is unital. For the second part of the theorem let us note that any unital \*-homomorphism  $\varphi: A \to B$  is full and if two unital \*-homomorphisms  $\varphi, \psi: A \to B$  are asymptotically unitarily equivalent when regarded as maps into  $B \otimes \mathcal{K}$ , then  $\varphi \approx_{uh} \psi$  when regarded as maps into B, by an argument from the proof of [28, Thm. 4.1.4].

A separable nonzero C\*-algebra D is semiprojective [1] if for any separable C\*-algebra A and any increasing sequence of two-sided closed ideals  $(J_n)$  of A with  $J = \overline{\bigcup_n J_n}$ , the natural map  $\varinjlim \operatorname{Hom}(D, A/J_n) \to \operatorname{Hom}(D, A/J)$  (induced by  $\pi_n : A/J_n \to A/J$ ) is surjective. If we weaken this condition and require only that the above map has dense range, where  $\operatorname{Hom}(D, A/J)$  is given the point-norm topology, then D is called weakly semiprojective [14]. These definitions do not change if we drop the separability of A. We shall use (weak) semiprojectivity in the following context. Let A be a C(X)-algebra (with X metrizable), let  $X \in X$  and set  $X \in Y$  and set  $X \in$ 

**Examples 3.2** (Weakly semiprojective  $C^*$ -algebras). Any finite dimensional  $C^*$ -algebra is semiprojective. A Kirchberg algebra D satisfying the UCT and having finitely generated K-theory groups is weakly semiprojective by work of Neubüser [26], H. Lin [24] and Spielberg [32]. This also follows from Theorem 3.12 and Proposition 3.14 below. If in addition  $K_1(D)$  is torsion free, then D is semiprojective as proved by Spielberg [33] who extended the foundational work of Blackadar [1] and Szymański [34].

The following generalizations of two results of Loring [25] are used in Section 5; see [10].

**Proposition 3.3.** Let D be a separable semiprojective  $C^*$ -algebra. For any finite set  $\mathcal{F} \subset D$  and any  $\varepsilon > 0$ , there exist a finite set  $\mathcal{G} \subset D$  and  $\delta > 0$  with the following property. Let  $\pi : A \to B$  be a surjective \*-homomorphism, and let  $\varphi : D \to B$  and  $\gamma : D \to A$  be \*-homomorphisms such that  $\|\pi \gamma(d) - \varphi(d)\| < \delta$  for all  $d \in \mathcal{G}$ . Then there is a \*-homomorphism  $\psi : D \to A$  such that  $\pi \psi = \varphi$  and  $\|\gamma(c) - \psi(c)\| < \varepsilon$  for all  $c \in \mathcal{F}$ .

**Proposition 3.4.** Let D be a separable semiprojective  $C^*$ -algebra. For any finite set  $\mathcal{F} \subset D$  and any  $\varepsilon > 0$ , there exist a finite set  $\mathcal{G} \subset D$  and  $\delta > 0$  with the following property. For any two \*-homomorphisms  $\varphi, \psi : D \to B$  such that  $\|\varphi(d) - \psi(d)\| < \delta$  for all  $d \in \mathcal{G}$ , there is a homotopy  $\Phi \in \text{Hom}(D, C[0, 1] \otimes B)$  such that  $\Phi_0 = \varphi$  to  $\Phi_1 = \psi$  and  $\|\varphi(c) - \Phi_t(c)\| < \varepsilon$  for all  $c \in \mathcal{F}$  and  $t \in [0, 1]$ .

**Definition 3.5.** A separable C\*-algebra D is KK-stable if there is a finite set  $\mathcal{G} \subset D$  and there is  $\delta > 0$  with the property that for any two \*-homomorphisms  $\varphi, \psi : D \to A$  such that  $\|\varphi(a) - \psi(a)\| < \delta$  for all  $a \in \mathcal{G}$ , one has  $KK(\varphi) = KK(\psi)$ .

**Corollary 3.6.** Any semiprojective C\*-algebra is weakly semiprojective and KK-stable.

**Proof.** This follows from Proposition 3.4.  $\Box$ 

**Proposition 3.7.** Let D be a separable weakly semiprojective  $C^*$ -algebra. For any finite set  $\mathcal{F} \subset D$  and any  $\varepsilon > 0$  there exist a finite set  $\mathcal{G} \subset D$  and  $\delta > 0$  such that for any  $C^*$ -algebras  $B \subset A$  and any  $\varepsilon$ -homomorphism  $\varphi : D \to A$  with  $\varphi(\mathcal{G}) \subset_{\delta} B$ , there is a  $\varepsilon$ -homomorphism  $\varphi : D \to B$  such that  $\|\varphi(c) - \psi(c)\| < \varepsilon$  for all  $c \in \mathcal{F}$ . If in addition D is KK-stable, then we can choose  $\mathcal{G}$  and  $\delta$  such that we also have  $KK(\psi) = KK(\varphi)$ .

**Proof.** This follows from [14, Thms. 3.1, 4.6]. Since the result is essential to us we include a short proof. Fix  $\mathcal{F}$  and  $\varepsilon$ . Let  $(\mathcal{G}_n)$  be an increasing sequence of finite subsets of D whose union is dense in D. If the statement is not true, then there are sequences of  $C^*$ -algebras  $C_n \subset A_n$  and \*-homomorphisms  $\varphi_n : D \to A_n$  satisfying  $\varphi_n(\mathcal{G}_n) \subset_{1/n} C_n$  and with the property that for any  $n \ge 1$  there is no \*-homomorphism  $\psi_n : D \to C_n$  such that  $\|\varphi_n(c) - \psi_n(c)\| < \varepsilon$  for all  $c \in \mathcal{F}$ . Set  $B_i = \prod_{n \ge i} A_n$  and  $E_i = \prod_{n \ge i} C_n \subset B_i$ . If  $v_i : B_i \to B_{i+1}$  is the natural projection, then  $v_i(E_i) = E_{i+1}$ . Let us observe that if we define  $\Phi_i : D \to B_i$  by  $\Phi_i(d) = (\varphi_i(d), \varphi_{i+1}(d), \ldots)$ , then the image of  $\Phi = \varinjlim \Phi_i : D \to \varinjlim (B_i, v_i)$  is contained in  $\varinjlim (E_i, v_i)$ . Since D is weakly semiprojective, there is i and a \*-homomorphism  $\Psi_i : D \to E_i$ , of the form  $\Psi_i(d) = (\psi_i(d), \psi_{i+1}(d), \ldots)$  such that  $\|\Phi_i(c) - \Psi_i(c)\| < \varepsilon$  for all  $c \in \mathcal{F}$ . Therefore  $\|\varphi_i(c) - \psi_i(c)\| < \varepsilon$  for all  $c \in \mathcal{F}$  which gives a contradiction.  $\square$ 

It is useful to combine Propositions 3.7 and 3.3 in a single statement.

**Proposition 3.8.** Let D be a separable semiprojective  $C^*$ -algebra. For any finite set  $\mathcal{F} \subset D$  and any  $\varepsilon > 0$ , there exist a finite set  $\mathcal{G} \subset D$  and  $\delta > 0$  with the following property. Let  $\pi: A \to B$  be a surjective \*-homomorphism which maps a  $C^*$ -subalgebra A' of A onto a  $C^*$ -subalgebra B' of B. Let  $\varphi: D \to B'$  and  $\gamma: D \to A$  be \*-homomorphisms such that  $\gamma(\mathcal{G}) \subset_{\delta} A'$ 

and  $\|\pi\gamma(d) - \varphi(d)\| < \delta$  for all  $d \in \mathcal{G}$ . Then there is a \*-homomorphism  $\psi : D \to A'$  such that  $\pi\psi = \varphi$  and  $\|\gamma(c) - \psi(c)\| < \varepsilon$  for all  $c \in \mathcal{F}$ .

**Proof.** Let  $\mathcal{G}_L$  and  $\delta_L$  be given by Proposition 3.3 applied to the input data  $\mathcal{F}$  and  $\varepsilon/2$ . We may assume that  $\mathcal{F} \subset \mathcal{G}_L$  and  $\varepsilon > \delta_L$ . Next, let  $\mathcal{G}_P$  and  $\delta_P$  be given by Proposition 3.7 applied to the input data  $\mathcal{G}_L$  and  $\delta_L/2$ . We show now that  $\mathcal{G} := \mathcal{G}_L \cup \mathcal{G}_P$  and  $\delta := \min\{\delta_P, \delta_L/2\}$  have the desired properties. We have  $\gamma(\mathcal{G}_P) \subset_{\delta_P} A'$  since  $\mathcal{G}_P \subset \mathcal{G}$  and  $\delta \leqslant \delta_P$ . By Proposition 3.7 there is a \*-homomorphism  $\gamma' : D \to A'$  such that  $\|\gamma'(d) - \gamma(d)\| < \delta_L/2$  for all  $d \in \mathcal{G}_L$ . Then, since  $\mathcal{G}_L \subset \mathcal{G}$  and  $\delta \leqslant \delta_L/2$ ,

$$\|\pi\gamma'(d) - \varphi(d)\| \leq \|\pi\gamma'(d) - \pi\gamma(d)\| + \|\pi\gamma(d) - \varphi(d)\| < \delta_L/2 + \delta \leq \delta_L$$

for all  $d \in \mathcal{G}_L$ . Therefore we can invoke Proposition 3.3 to perturb  $\gamma'$  to a \*-homomorphism  $\psi: D \to A'$  such that  $\pi \psi = \varphi$  and  $\|\gamma'(d) - \psi(d)\| < \varepsilon/2$  for all  $d \in \mathcal{F}$ . Finally we observe that for  $d \in \mathcal{F} \subset \mathcal{G}_L$ 

$$\|\gamma(d) - \psi(d)\| \le \|\gamma(d) - \gamma'(d)\| + \|\gamma'(d) - \psi(d)\| < \delta_L/2 + \varepsilon/2 < \varepsilon.$$

**Definition 3.9.** (a) A separable C\*-algebra D is KK-semiprojective if for any separable C\*-algebra A and any increasing sequence of two-sided closed ideals  $(J_n)$  of A with  $J = \bigcup_n J_n$ , the natural map  $\lim_{n \to \infty} KK(D, A/J_n) \to KK(D, A/J)$  is surjective.

(b) We say that the functor KK(D, -) is *continuous* if for any inductive system  $B_1 \to B_2 \to \cdots$  of separable C\*-algebras, the induced map  $\lim KK(D, B_n) \to KK(D, \lim B_n)$  is bijective.

**Proposition 3.10.** Any separable KK-semiprojective C\*-algebra is KK-stable.

**Proof.** We shall prove the statement by contradiction. Let D be separable KK-semiprojective C\*-algebra. Let  $(\mathcal{G}_n)$  be an increasing sequence of finite subsets of D whose union is dense in D. If the statement is not true, then there are sequences of \*-homomorphisms  $\varphi_n, \psi_n : D \to A_n$  such that  $\|\varphi_n(d) - \psi_n(d)\| < 1/n$  for all  $d \in \mathcal{G}_n$  and yet  $KK(\varphi_n) \neq KK(\psi_n)$  for all  $n \geqslant 1$ . Set  $B_i = \prod_{n \geqslant i} A_n$  and let  $v_i : B_i \to B_{i+1}$  be the natural projection. Let us define  $\Phi_i, \Psi_i : D \to B_i$  by  $\Phi_i(d) = (\varphi_i(d), \varphi_{i+1}(d), \ldots)$  and  $\Psi_i(d) = (\psi_i(d), \psi_{i+1}(d), \ldots)$ , for all d in D. Let  $B_i'$  be the separable C\*-subalgebra of  $B_i$  generated by the images of  $\Phi_i$  and  $\Psi_i$ . Then  $v_i(B_i') = B_{i+1}'$  and one verifies immediately that  $\varinjlim \Phi_i = \varinjlim \Psi_i : D \to \varinjlim (B_i', v_i)$ . Since D is KK-semiprojective, we must have  $KK(\Phi_i) = KK(\Psi_i)$  for some i and hence  $KK(\varphi_n) = KK(\psi_n)$  for all  $n \geqslant i$ . This gives a contradiction.  $\square$ 

**Proposition 3.11.** A unital Kirchberg algebra D is KK-stable if and only if  $D \otimes K$  is KK-stable. D is weakly semiprojective if and only if  $D \otimes K$  is weakly semiprojective.

**Proof.** Since  $KK(D, A) \cong KK(D, A \otimes \mathcal{K}) \cong KK(D \otimes \mathcal{K}, A \otimes \mathcal{K})$  the first part of the proposition is immediate. Suppose now that  $D \otimes \mathcal{K}$  is weakly semiprojective. Then D is weakly semiprojective as shown in the proof of [32, Thm. 2.2]. Conversely, assume that D is weakly semiprojective. It suffices to find  $\alpha \in \text{Hom}(D \otimes \mathcal{K}, D)$  and a sequence  $(\beta_n)$  in  $\text{Hom}(D, D \otimes \mathcal{K})$  such that  $\beta_n \alpha$  converges to  $\text{id}_{D \otimes \mathcal{K}}$  in the point-norm topology. Let  $s_i$  be the canonical generators of  $\mathcal{O}_{\infty}$ . If  $(e_{ij})$  is a system of matrix units for  $\mathcal{K}$ , then  $\lambda(e_{ij}) = s_i s_j^*$  defines a \*-homomorphism  $\mathcal{K} \to \mathcal{O}_{\infty}$ 

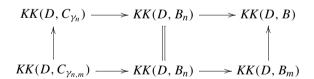

such that  $KK(\lambda) \in KK(\mathcal{K}, \mathcal{O}_{\infty})^{-1}$ . Therefore, by composing  $\mathrm{id}_D \otimes \lambda$  with some isomorphism  $D \otimes \mathcal{O}_{\infty} \cong D$  (given by [29, Thm. 7.6.6]) we obtain a \*-monomorphism  $\alpha : D \otimes \mathcal{K} \to D$  which induces a KK-equivalence. Let  $\beta : D \to D \otimes \mathcal{K}$  be defined by  $\beta(d) = d \otimes e_{11}$ . Then  $\beta\alpha \in \mathrm{End}(D \otimes \mathcal{K})$  induces a KK-equivalence and hence after replacing  $\beta$  by  $\theta\beta$  for some automorphism  $\theta$  of  $D \otimes \mathcal{K}$ , we may arrange that  $KK(\beta\alpha) = KK(\mathrm{id}_D)$ . By Theorem 3.1,  $\beta\alpha \approx_u \mathrm{id}_{D \otimes \mathcal{K}}$ , so that there is a sequence of unitaries  $u_n \in (D \otimes \mathcal{K})^+$  such that  $u_n\beta\alpha(-)u_n^*$  converges to  $\mathrm{id}_{D \otimes \mathcal{K}}$ .  $\square$ 

**Theorem 3.12.** For a separable  $C^*$ -algebra D consider the following properties:

- (i) D is KK-semiprojective.
- (ii) The functor KK(D, -) is continuous.
- (iii) *D* is weakly semiprojective and KK-stable.

Then (i)  $\Leftrightarrow$  (ii). Moreover, (iii)  $\Rightarrow$  (i) if D is nuclear and (i)  $\Rightarrow$  (iii) if D is a Kirchberg algebra. Thus (i)  $\Leftrightarrow$  (ii)  $\Leftrightarrow$  (iii) for any Kirchberg algebra D.

**Proof.** The implication (ii)  $\Rightarrow$  (i) is obvious. (i)  $\Rightarrow$  (ii): Let  $(B_n, \gamma_{n,m})$  be an inductive system with inductive limit B and let  $\gamma_n: B_n \to B$  be the canonical maps. We have an induced map  $\beta: \varinjlim KK(D, B_n) \to KK(D, B)$ . First we show that  $\beta$  is surjective. The mapping telescope construction of L.G. Brown (as described in the proof of [1, Thm. 3.1]) produces an inductive system of C\*-algebras  $(T_n, \eta_{n,m})$  with inductive limit B such that each  $\eta_{n,n+1}$  is surjective, and each canonical map  $\eta_n: T_n \to B$  is homotopic to  $\gamma_n \alpha_n$  for some \*-homomorphism  $\alpha_n: T_n \to B_n$ . In particular  $KK(\eta_n) = KK(\gamma_n)KK(\alpha_n)$ . Let  $x \in KK(D, B)$ . By (i) there are n and  $y \in KK(D, T_n)$  such that  $KK(\eta_n)y = x$  and hence  $KK(\gamma_n)KK(\alpha_n)y = x$ . Thus  $z = KK(\alpha_n)y \in KK(D, B_n)$  is a lifting of x. Let us show now that the map  $\beta$  is injective. Let x be an element in the kernel of the map  $KK(D, B_n) \to KK(D, B)$ . Consider the commutative diagram whose exact rows are portions of the Puppe sequence in K-theory [2, Thm. 19.4.3] and with vertical maps induced by  $\gamma_m: B_m \to B, m \geqslant n$ .

By exactness, x is the image of some element  $y \in KK(D, C_{\gamma_n})$ . Since  $C_{\gamma_n} = \varinjlim C_{\gamma_{n,m}}$ , the map  $\varinjlim KK(D, C_{\gamma_{n,m}}) \to KK(D, C_{\gamma_n})$  is surjective by the first part of the proof. Therefore there is  $m \ge n$  such that y lifts to some  $z \in KK(D, C_{\gamma_{n,m}})$ . The image of z in  $KK(D, B_m)$  equals  $KK(\gamma_{n,m})x$  and vanishes by exactness of the bottom row.

(iii)  $\Rightarrow$  (i): Let A,  $(J_n)$  and J be as in Definition 3.9. Using the five-lemma and the split exact sequence  $0 \to KK(D, A) \to KK(D, A^+) \to KK(D, \mathbb{C}) \to 0$ , we reduce the proof to the case when A is unital. Let  $x \in KK(D, A/J)$ . Since the map  $KK(D^+, A/J) \to KK(D, A/J)$  is surjective, x lifts to some element  $x^+ \in KK(D^+, A/J)$ . By [29, Thm. 8.3.3], since  $D^+$  is nuclear, there is a \*-homomorphism  $\Phi: D^+ \to A/J \otimes \mathcal{O}_{\infty} \otimes \mathcal{K}$  such that  $KK(\Phi) = x^+$  and hence if set  $\varphi = \Phi|_D$ , then  $KK(\varphi) = x$ . Since D is weakly semiprojective, there are n and a \*-homomorphism  $\psi: D \to A/J_n \otimes \mathcal{O}_{\infty} \otimes \mathcal{K}$  such that  $\|\pi_n \psi(d) - \varphi(d)\| < \delta$  for all  $d \in \mathcal{G}$ , where

 $\mathcal{G}$  and  $\delta$  are as in the definition of KK-stability. Therefore  $KK(\pi_n\psi) = KK(\varphi)$  and hence  $KK(\psi)$  is a lifting of x to  $KK(D, A/J_n)$ .

(i)  $\Rightarrow$  (iii): D is KK-stable by Proposition 3.10. It remains to show that D is weakly semiprojective. Since any nonunital Kirchberg algebra is isomorphic to the stabilization of a unital one (see [29, Prop. 4.1.3]) and since by Proposition 3.11 D is KK-semiprojective if and only if  $D \otimes K$  is KK-semiprojective, we may assume that D is unital. Let A,  $(J_n)$ ,  $\pi_{m,n}: A/J_m \to A/J_n$   $(m \leqslant n)$  and  $\pi_n: A/J_n \to A/J$  be as in the definition of weak semiprojectivity. By [1, Cor. 2.15], we may assume that A and the \*-homomorphism  $\varphi: D \to A$  (for which we want to construct an approximative lifting) are unital. In particular  $\varphi$  is injective since D is simple. Set  $B = \varphi(D) \subset A/J$  and  $B_n = \pi_n^{-1}(B) \subset A/J_n$ . The corresponding maps  $\pi_{m,n}: B_m \to B_n$   $(m \leqslant n)$  and  $\pi_n: B_n \to B$  are surjective and they induce an isomorphism  $\lim_{n \to \infty} (B_n, \pi_{n,n+1}) \cong B$ . Given  $\varepsilon > 0$  and  $\mathcal{F} \subset D$  (a finite set) we are going to produce an approximate lifting  $\varphi_n: D \to B_n$  for  $\varphi$ . Since  $1_B$  is a properly infinite projection, it follows by [1, Props. 2.18 and 2.23] that the unit  $1_n$  of  $B_n$  is a properly infinite projection, for all sufficiently large n. Since D is KK-semiprojective, there exist m and an element  $h \in KK(D, B_m)$  which lifts  $KK(\varphi)$  such that  $K_0(h)[1_D] = [1_m]$ . By [29, Thm. 8.3.3], there is a full \*-homomorphism  $\eta: D \to B_m \otimes K$  such that  $KK(\eta) = h$ . By [29, Prop. 4.1.4], since both  $\eta(1_D)$  and  $1_m$  are full and properly in-

finite projections in  $B_m \otimes \mathcal{K}$ , there is a partial isometry  $w \in B_m \otimes \mathcal{K}$  such that  $w^*w = \eta(1_D)$  and  $ww^* = 1_m$ . Replacing  $\eta$  by  $w\eta(-)w^*$ , we may assume that  $\eta: D \to B_m$  is unital. Then  $KK(\pi_m \eta) = KK(\pi_m)h = KK(\varphi)$ . By Theorem 3.1,  $\pi_m \eta \approx_{uh} \varphi$ . Thus there is a unitary  $u \in B$  such that  $\|u\pi_m \eta(d)u^* - \varphi(d)\| < \varepsilon$  for all  $d \in \mathcal{F}$ . Since  $C(\mathbb{T})$  is semiprojective, there is  $n \geqslant m$  such that u lifts to a unitary  $u_n \in B_n$ . Then  $\varphi_n := u_n \pi_{m,n} \eta(-) u_n^*$  is a \*-homomorphism from D to  $B_n$  such that  $\|\pi_n \varphi_n(d) - \varphi(d)\| < \varepsilon$  for all  $d \in \mathcal{F}$ .  $\square$ 

**Corollary 3.13.** Any separable nuclear semiprojective C\*-algebra is KK-semiprojective.

**Proof.** This is very similar to the proof of the implication (iii)  $\Rightarrow$  (i) of Theorem 3.12. Alternatively, the statement follows from Corollary 3.6 and Theorem 3.12.  $\Box$ 

Blackadar has shown that a semiprojective Kirchberg algebra satisfying the UCT has finitely generated K-theory groups [29, Prop. 8.4.15]. A similar argument gives the following:

**Proposition 3.14.** Let D be a separable  $C^*$ -algebra satisfying the UCT. Then D is KK-semiprojective if and only  $K_*(D)$  is finitely generated.

**Proof.** If  $K_*(D)$  is finitely generated, then D is KK-semiprojective by [31]. Conversely, assume that D is KK-semiprojective. Since D satisfies the UCT, we infer that if  $G = K_i(D)$  (i = 0, 1), then G is semiprojective in the category of countable abelian groups, in the sense that if  $H_1 \to H_2 \to \cdots$  is an inductive system of countable abelian groups with inductive limit H, then the natural map  $\varinjlim \operatorname{Hom}(G, H_n) \to \operatorname{Hom}(G, H)$  is surjective. This implies that G is finitely generated. Indeed, taking H = G, we see that  $\operatornamewithlimits{id}_G$  lifts to  $\operatornamewithlimits{Hom}(G, H_n)$  for some finitely generated subgroup  $H_n$  of G and hence G is a quotient of  $H_n$ .  $\square$ 

#### 4. Approximation of C(X)-algebras

In this section we use weak semiprojectivity to approximate a continuous C(X)-algebra A by C(X)-subalgebras given by pullbacks of n-fibered monomorphisms into A.

**Lemma 4.1.** Let D be a finite direct sum of simple  $C^*$ -algebras and let  $\varphi, \psi : D \to A$  be \*-homomorphisms. Suppose that  $\mathcal{H} \subset D$  contains a nonzero element from each simple direct summand of D. If  $\|\psi(d) - \varphi(d)\| \le \|d\|/2$  for all  $d \in \mathcal{H}$ , then  $\varphi$  is injective if and only if  $\psi$  is injective.

**Proof.** Let us note that  $\varphi$  is injective if and only if  $\|\varphi(d)\| = \|d\|$  for all  $d \in \mathcal{H}$ . Therefore if  $\varphi$  is injective, then  $\|\psi(d)\| \geqslant \|\varphi(d)\| - \|\psi(d) - \varphi(d)\| \geqslant \|d\|/2$  for all  $d \in \mathcal{H}$  and hence  $\psi$  is injective.  $\square$ 

A sequence  $(A_n)$  of subalgebras of A is called *exhaustive* if for any finite subset  $\mathcal{F}$  of A and any  $\varepsilon > 0$  there is n such that  $\mathcal{F} \subset_{\varepsilon} A_n$ .

**Lemma 4.2.** Let C be a class consisting of finite direct sums of separable simple weakly semiprojective  $C^*$ -algebras. Let X be a compact metrizable space and let A be a C(X)-algebra. Let  $\mathcal{F} \subset A$  be a finite set, let  $\varepsilon > 0$  and suppose that A(x) admits an exhaustive sequence of  $C^*$ -algebras isomorphic to  $C^*$ -algebras in C for some  $x \in X$ . Then there exist a compact neighborhood U of x and a \*-homomorphism  $\varphi: D \to A(U)$  for some  $D \in C$  such that  $\pi_U(\mathcal{F}) \subset_{\varepsilon} \varphi(D)$ . If A is a continuous C(X)-algebra, then we may arrange that  $\varphi_z$  is injective for all  $z \in U$ .

**Proof.** Let  $\mathcal{F} = \{a_1, \ldots, a_r\}$  and  $\varepsilon$  be given. By hypothesis there exist  $D \in \mathcal{C}$ ,  $\{c_1, \ldots, c_r\} \subset D$  and a \*-monomorphism  $\iota: D \to A(x)$  such that  $\|\pi_x(a_i) - \iota(c_i)\| < \varepsilon/2$ , for all  $i = 1, \ldots, r$ . Set  $U_n = \{y \in X: d(x,y) \leqslant 1/n\}$ . Choose a full element  $d_j$  in each direct summand of D. Since D is weakly semiprojective, there is a \*-homomorphism  $\varphi: D \to A(U_n)$  (for some n) such that  $\|\pi_x \varphi(c_i) - \iota(c_i)\| < \varepsilon/2$  for all  $i = 1, \ldots, r$ , and  $\|\pi_x \varphi(d_j) - \iota(d_j)\| \leqslant \|d_j\|/2$  for all  $d_j$ . Therefore

$$\|\pi_{x}\varphi(c_{i}) - \pi_{x}(a_{i})\| \leq \|\pi_{x}\varphi(c_{i}) - \iota(c_{i})\| + \|\pi_{x}(a_{i}) - \iota(c_{i})\| < \varepsilon/2 + \varepsilon/2 = \varepsilon$$

and  $\varphi_x$  is injective by Lemma 4.1. By Lemma 2.1(i), after increasing n and setting  $U = U_n$  and  $\varphi = \pi_U \varphi$ , we have

$$\|\varphi(c_i) - \pi_U(a_i)\| = \|\pi_U(\varphi(c_i) - a_i)\| < \varepsilon,$$

for all  $i=1,\ldots,r$ . This shows that  $\pi_U(\mathcal{F})\subset_{\varepsilon}\varphi(D)$ . If A is continuous, then after shrinking U we may arrange that  $\|\varphi_z(d_j)\|\geqslant \|\varphi_x(d_j)\|/2=\|d_j\|/2$  for all  $d_j$  and all  $z\in U$ . This implies that  $\varphi_z$  in injective for all  $z\in U$ .  $\square$ 

**Lemma 4.3.** Let X be a compact metrizable space and let A be a separable continuous C(X)-algebra the fibers of which are stable Kirchberg algebras. Let  $\mathcal{F} \subset A$  be a finite set and let  $\varepsilon > 0$ . Suppose that there exist a KK-semiprojective stable Kirchberg algebra D and  $\sigma \in KK(D, A)$  such that  $\sigma_x \in KK(D, A(x))^{-1}$  for some  $x \in X$ . Then there exist a closed neighborhood U of x and a full \*-homomorphism  $\psi : D \to A(U)$  such that  $KK(\psi) = \sigma_U$  and  $\pi_U(\mathcal{F}) \subset_{\varepsilon} \psi(D)$ .

**Proof.** By [29, Thm. 8.4.1] there is an isomorphism  $\psi_0: D \to A(x)$  such that  $KK(\psi_0) = \sigma_x$ . Let  $\mathcal{H} \subset D$  be such that  $\psi_0(\mathcal{H}) = \pi_x(\mathcal{F})$ . Set  $U_n = \{y \in X : d(x, y) \le 1/n\}$ . By Theorem 3.12 D is KK-stable and weakly semiprojective. By Proposition 3.7 there exists a \*-homomorphism  $\psi_n: D \to A(U_n)$  (for some n) such that  $\|\pi_x \psi_n(d) - \psi_0(d)\| < \varepsilon$  for all  $d \in \mathcal{H}$  and  $KK(\pi_x \psi_n) = 0$   $KK(\psi_0) = \sigma_X$ . Since  $\lim_m KK(D, A(U_m)) = KK(D, A(X))$ , we deduce that there is  $m \ge n$  such that  $KK(\pi_{U_m}\psi_n) = \sigma_{U_m}$ . By increasing m we may arrange that  $\pi_{U_m}(\mathcal{F}) \subset_{\varepsilon} \pi_{U_m}\psi_n(D)$  since we have seen that  $\pi_x(\mathcal{F}) = \psi_0(\mathcal{H}) \subset_{\varepsilon} \pi_x \psi_n(D)$ . We can arrange that  $\psi_z$  is injective for all  $z \in U$  by reasoning as in the proof of Lemma 4.2. We conclude by setting  $U = U_m$  and  $\psi = \pi_{U_m} \psi_n$ .

The following lemma is useful for constructing fibered morphisms.

**Lemma 4.4.** Let  $(D_i)_{i \in J}$  be a finite family consisting of finite direct sums of weakly semiprojective simple  $C^*$ -algebras. Let  $\varepsilon > 0$  and for each  $j \in J$  let  $\mathcal{H}_i \subset D_j$  be a finite set such that for each direct summand of  $D_i$  there is an element of  $\mathcal{H}_i$  of norm  $\geq \varepsilon$  which is contained and is full in that summand. Let  $\mathcal{G}_i \subset D_i$  and  $\delta_i > 0$  be given by Proposition 3.7 applied to  $D_i$ ,  $\mathcal{H}_i$ and  $\varepsilon/2$ . Let X be a compact metrizable space, let  $(Z_i)_{i\in J}$  be disjoint nonempty closed subsets of X and let Y be a closed nonempty subset of X such that  $X = Y \cup (\bigcup_i Z_i)$ . Let A be a continuous C(X)-algebra and let  $\mathcal{F}$  be a finite subset of A. Let  $\eta: B(Y) \to A(Y)$  be a \*-monomorphism of C(Y)-algebras and let  $\varphi_j: D_j \to A(Z_j)$  be \*-homomorphisms such that  $(\varphi_j)_x$  is injective for all  $x \in Z_j$  and  $j \in J$ , and which satisfy the following conditions:

- $\begin{array}{ll} \text{(i)} & \pi_{Z_j}(\mathcal{F}) \subset_{\varepsilon/2} \varphi_j(\mathcal{H}_j), \textit{for all } j \in J, \\ \text{(ii)} & \pi_Y(\mathcal{F}) \subset_\varepsilon \eta(B), \\ \text{(iii)} & \pi_{Y \cap Z_j}^{Z_j} \varphi_j(\mathcal{G}_j) \subset_{\delta_j} \pi_{Y \cap Z_j}^Y \eta(B), \textit{for all } j \in J. \end{array}$

Then, there are  $C(Z_j)$ -linear \*-monomorphisms  $\psi_j : C(Z_j) \otimes D_j \to A(Z_j)$ , satisfying

$$\|\varphi_i(c) - \psi_i(c)\| < \varepsilon/2, \quad \text{for all } c \in \mathcal{H}_i, \text{ and } j \in J,$$
 (6)

and such that if we set  $E = \bigoplus_j C(Z_j) \otimes D_j$ ,  $Z = \bigcup_j Z_j$ , and  $\psi : E \to A(Z) = \bigoplus_j A(Z_j)$ ,  $\psi = \bigoplus_i \psi_i$ , then  $\pi_{Y \cap Z}^Z(\psi(E)) \subseteq \pi_{Y \cap Z}^Y(\eta(B))$ ,  $\pi_Z(\mathcal{F}) \subset_{\varepsilon} \psi(E)$  and hence

$$\mathcal{F} \subset_{\varepsilon} \eta(B) \oplus_{Y \cap Z} \psi(E) = \chi(B \oplus_{\pi \eta, \pi \psi} E),$$

where  $\chi$  is the isomorphism induced by the pair  $(\eta, \psi)$ . If we assume that each  $D_i$  is KK-stable, then we also have  $KK(\varphi_i) = KK(\psi_i|_{D_i})$  for all  $j \in J$ .

**Proof.** Let  $\mathcal{F} = \{a_1, \dots, a_r\} \subset A$  be as in the statement. By (i), for each  $j \in J$  we find  $\{c_1^{(j)}, \ldots, c_r^{(j)}\} \subseteq \mathcal{H}_j$  such that  $\|\varphi_j(c_i^{(j)}) - \pi_{Z_j}(a_i)\| < \varepsilon/2$  for all i. Consider the C(X)-algebra  $A \oplus_Y \eta(B) \subset A$ . From (iii), Lemma 2.1(iv) and Lemma 2.5 we obtain

$$\varphi_j(\mathcal{G}_j) \subset_{\delta_j} \pi_{Z_j}(A \oplus_Y \eta(B)).$$

Applying Proposition 3.7 we perturb  $\varphi_j$  to a \*-homomorphism  $\psi_j: D_j \to \pi_{Z_j}(A \oplus_Y \eta(B))$ satisfying (6), and hence such that  $\|\varphi_j(c_i^{(j)}) - \psi_j(c_i^{(j)})\| < \varepsilon/2$ , for all i, j. Therefore

$$\|\psi_{j}(c_{i}^{(j)}) - \pi_{Z_{j}}(a_{i})\| \leq \|\psi_{j}(c_{i}^{(j)}) - \varphi_{j}(c_{i}^{(j)})\| + \|\varphi_{j}(c_{i}^{(j)}) - \pi_{Z_{j}}(a_{i})\| < \varepsilon.$$

This shows that  $\pi_{Z_i}(\mathcal{F}) \subset_{\varepsilon} \psi_i(D_i)$ . From (6) and Lemma 4.1 we obtain that each  $(\psi_i)_x$  is injective. We extend  $\psi_i$  to a  $C(Z_i)$ -linear \*-monomorphism  $\psi_i: C(Z_i) \otimes D_i \rightarrow$ 

 $\pi_{Z_j}(A \oplus_Y \eta(B))$  and then we define E,  $\psi$  and Z as in the statement. In this way we obtain that  $\psi: E \to (A \oplus_Y \eta(B))(Z) \subset A(Z)$  satisfies

$$\pi_Z(\mathcal{F}) \subset_{\varepsilon} \psi(E).$$
 (7)

The property  $\psi(E) \subset (A \oplus_Y \eta(B))(Z)$  is equivalent to  $\pi_{Y \cap Z}^Z(\psi(E)) \subseteq \pi_{Y \cap Z}^Y(\eta(B))$  by Lemma 2.6(b). Finally, from (ii), (7) and Lemma 2.6(c) we get  $\mathcal{F} \subset_{\varepsilon} \eta(B) \oplus_{Y \cap Z} \psi(E)$ .  $\square$ 

Let  $\mathcal{C}$  be as in Lemma 4.2. Let A be a C(X)-algebra, let  $\mathcal{F} \subset A$  be a finite set and let  $\varepsilon > 0$ . An  $(\mathcal{F}, \varepsilon, \mathcal{C})$ -approximation of A

$$\alpha = \left\{ \mathcal{F}, \varepsilon, \left\{ U_i, \varphi_i : D_i \to A(U_i), \mathcal{H}_i, \mathcal{G}_i, \delta_i \right\}_{i \in I} \right\}, \tag{8}$$

is a collection with the following properties:  $(U_i)_{i\in I}$  is a finite family of closed subsets of X, whose interiors cover X and  $(D_i)_{i\in I}$  are C\*-algebras in  $\mathcal{C}$ ; for each  $i\in I$ ,  $\varphi_i:D_i\to A(U_i)$  is a \*-homomorphism such that  $(\varphi_i)_X$  is injective for all  $X\in U_i$ ;  $\mathcal{H}_i\subset D_i$  is a finite set such that  $\pi_{U_i}(\mathcal{F})\subset_{\varepsilon/2}\varphi_i(\mathcal{H}_i)$  and such that for each direct summand of  $D_i$  there is an element of  $\mathcal{H}_i$  of norm  $\geqslant \varepsilon$  which is contained and is full in that summand; the finite set  $\mathcal{G}_i\subset D_i$  and  $\delta_i>0$  are given by Proposition 3.7 applied to the weakly semiprojective C\*-algebra  $D_i$  for the input data  $\mathcal{H}_i$  and  $\varepsilon/2$ ; if  $D_i$  is KK-stable, then  $\mathcal{G}_i$  and  $\delta_i$  are chosen such that the second part of Proposition 3.7 also applies.

**Lemma 4.5.** Let A and C be as in Lemma 4.2. Suppose that each fiber of A admits an exhaustive sequence of  $C^*$ -algebras isomorphic to  $C^*$ -algebras in C. Then for any finite subset F of A and any  $\varepsilon > 0$  there is an  $(F, \varepsilon, C)$ -approximation of A. Moreover, if A, D and  $\sigma$  are as in Lemma 4.3 and  $\sigma_x \in KK(D, A(x))^{-1}$  for all  $x \in X$ , then there is an  $(F, \varepsilon, C)$ -approximation of A such that  $C = \{D\}$  and  $KK(\varphi_i) = \sigma_{U_i}$  for all  $i \in I$ .

**Proof.** Since *X* is compact, this is an immediate consequence of Lemmas 4.2, 4.3 and Proposition 3.7.  $\Box$ 

It is useful to consider the following operation of restriction. Suppose that Y is a closed subspace of X and let  $(V_j)_{j \in J}$  be a finite family of closed subsets of Y which refines the family  $(Y \cap U_i)_{i \in I}$  and such that the interiors of the  $V_j$ 's form a cover of Y. Let  $\iota: J \to I$  be a map such that  $V_j \subseteq Y \cap U_{\iota(j)}$ . Define

$$\iota^*(\alpha) = \left\{ \pi_Y(\mathcal{F}), \varepsilon, \left\{ V_j, \pi_{V_j} \varphi_{\iota(j)} : D_{\iota(j)} \to A(V_j), \mathcal{H}_{\iota(j)}, \mathcal{G}_{\iota(j)}, \delta_{\iota(j)} \right\}_{j \in J} \right\}.$$

It is obvious that  $\iota^*(\alpha)$  is a  $(\pi_Y(\mathcal{F}), \varepsilon, \mathcal{C})$ -approximation of A(Y). The operation  $\alpha \mapsto \iota^*(\alpha)$  is useful even in the case X = Y. Indeed, by applying this procedure we can refine the cover of X that appears in a given  $(\mathcal{F}, \varepsilon, \mathcal{C})$ -approximation of A.

An  $(\mathcal{F}, \varepsilon, \mathcal{C})$ -approximation  $\alpha$  (as in (8)) is subordinated to an  $(\mathcal{F}', \varepsilon', \mathcal{C})$ -approximation,  $\alpha' = \{\mathcal{F}', \varepsilon', \{U_{i'}, \varphi_{i'} : D_{i'} \to A(U_{i'}), \mathcal{H}_{i'}, \mathcal{G}_{i'}, \delta_{i'}\}_{i' \in I'}\}$ , written  $\alpha \prec \alpha'$ , if

- (i)  $\mathcal{F} \subset \mathcal{F}'$ ,
- (ii)  $\varphi_i(\mathcal{G}_i) \subseteq \pi_{U_i}(\mathcal{F}')$  for all  $i \in I$ , and
- (iii)  $\varepsilon' < \min(\{\varepsilon\} \cup \{\delta_i, i \in I\}).$

Let us note that, with notation as above, we have  $\iota^*(\alpha) \prec \iota^*(\alpha')$  whenever  $\alpha \prec \alpha'$ .

The following theorem is the crucial technical result of our paper. It provides an approximation of continuous C(X)-algebras by subalgebras of category  $\leq \dim(X)$ .

**Theorem 4.6.** Let C be a class consisting of finite direct sums of weakly semiprojective simple  $C^*$ -algebras. Let X be a finite dimensional compact metrizable space and let A be a separable continuous C(X)-algebra the fibers of which admit exhaustive sequences of  $C^*$ -algebras isomorphic to  $C^*$ -algebras in C. For any finite set  $F \subset A$  and any  $\varepsilon > 0$  there exist  $n \leq \dim(X)$  and an n-fibered C-monomorphism  $(\psi_0, \ldots, \psi_n)$  into A which induces a \*-monomorphism  $\eta: A(\psi_0, \ldots, \psi_n) \to A$  such that  $F \subset_{\varepsilon} \eta(A(\psi_0, \ldots, \psi_n))$ .

**Proof.** By Lemma 4.5, for any finite set  $\mathcal{F} \subset A$  and any  $\varepsilon > 0$  there is an  $(\mathcal{F}, \varepsilon, \mathcal{C})$ -approximation of A. Moreover, for any finite set  $\mathcal{F} \subset A$ , any  $\varepsilon > 0$  and any n, there is a sequence  $\{\alpha_k \colon 0 \leqslant k \leqslant n\}$  of  $(\mathcal{F}_k, \varepsilon_k, \mathcal{C})$ -approximations of A such that  $(\mathcal{F}_0, \varepsilon_0) = (\mathcal{F}, \varepsilon)$  and  $\alpha_k$  is subordinated to  $\alpha_{k+1}$ :

$$\alpha_0 \prec \alpha_1 \prec \cdots \prec \alpha_n$$
.

Indeed, assume that  $\alpha_k$  was constructed. Let us choose a finite set  $\mathcal{F}_{k+1}$  which contains  $\mathcal{F}_k$  and liftings to A of all the elements in  $\bigcup_{i_k \in I_k} \varphi_{i_k}(\mathcal{G}_{i_k})$ . This choice takes care of the above conditions (i) and (ii). Next we choose  $\varepsilon_{k+1}$  sufficiently small such that (iii) is satisfied. Let  $\alpha_{k+1}$  be an  $(\mathcal{F}_{k+1}, \varepsilon_{k+1}, \mathcal{C})$ -approximation of A given by Lemma 4.5. Then obviously  $\alpha_k \prec \alpha_{k+1}$ . Fix a tower of approximations of A as above where  $n = \dim(X)$ .

By [4, Lemma 3.2], for every open cover  $\mathcal{V}$  of X there is a finite open cover  $\mathcal{U}$  which refines  $\mathcal{V}$  and such that the set  $\mathcal{U}$  can be partitioned into n+1 nonempty subsets consisting of elements with pairwise disjoint closures. Since we can refine simultaneously the covers that appear in a finite family  $\{\alpha_k \colon 0 \le k \le n\}$  of approximations while preserving subordination, we may arrange not only that all  $\alpha_k$  share the same cover  $(U_i)_{\in I}$ , but moreover, that the cover  $(U_i)_{i\in I}$  can be partitioned into n+1 subsets  $\mathcal{U}_0, \ldots, \mathcal{U}_n$  consisting of mutually disjoint elements. For definiteness, let us write  $\mathcal{U}_k = \{U_{i_k} \colon i_k \in I_k\}$ . Now for each k we consider the closed subset of X

$$Y_k = \bigcup_{i_k \in I_k} U_{i_k},$$

the map  $\iota_k: I_k \to I$  and the  $(\pi_{Y_k}(\mathcal{F}_k), \varepsilon_k, \mathcal{C})$ -approximation of  $A(Y_k)$ , induced by  $\alpha_k$ , which is of the form

$$\iota_k^*(\alpha_k) = \big\{ \pi_{Y_k}(\mathcal{F}_k), \varepsilon, \big\{ U_{i_k}, \varphi_{i_k} : D_{i_k} \to A(U_{i_k}), \mathcal{H}_{i_k}, \mathcal{G}_{i_k}, \delta_{i_k} \big\}_{i_k \in I_k} \big\},\,$$

where each  $U_{i_k}$  is nonempty. We have

$$\pi_{U_{i_k}}(\mathcal{F}_k) \subset_{\varepsilon_k/2} \varphi_{i_k}(\mathcal{H}_{i_k}),$$
 (9)

by construction. Since  $\alpha_k \prec \alpha_{k+1}$  we obtain

$$\mathcal{F}_k \subseteq \mathcal{F}_{k+1},\tag{10}$$

$$\varphi_{i_k}(\mathcal{G}_{i_k}) \subseteq \pi_{U_{i_k}}(\mathcal{F}_{k+1}), \quad \text{for all } i_k \in I_k,$$
 (11)

$$\varepsilon_{k+1} < \min(\{\varepsilon_k\} \cup \{\delta_{i_k}, i_k \in I_k\}).$$
 (12)

Set  $X_k = Y_k \cup \cdots \cup Y_n$  and  $E_k = \bigoplus_{i_k} C(U_{i_k}) \otimes D_{i_k}$  for  $0 \le k \le n$ . We shall construct a sequence of  $C(Y_k)$ -linear \*-monomorphisms,  $\psi_k : E_k \to A(Y_k), k = n, \ldots, 0$ , such that  $(\psi_k, \ldots, \psi_n)$  is an (n-k)-fibered monomorphism into  $A(X_k)$ . Each map

$$\psi_k = \bigoplus_{i_k} \psi_{i_k} : E_k \to A(Y_k) = \bigoplus_{i_k} A(U_{i_k})$$

will have components  $\psi_{i_k}: C(U_{i_k}) \otimes D_{i_k} \to A(U_{i_k})$  whose restrictions to  $D_{i_k}$  will be perturbations of  $\varphi_{i_k}: D_{i_k} \to A(U_{i_k})$ ,  $i_k \in I_k$ . We shall construct the maps  $\psi_k$  by induction on decreasing k such that if  $B_k = A(X_k)(\psi_k, \dots, \psi_n)$  and  $\eta_k: B_k \to A(X_k)$  is the map induced by the (n-k)-fibered monomorphism  $(\psi_k, \dots, \psi_n)$ , then

$$\pi_{X_{k+1}\cap U_{i_k}}\big(\psi_{i_k}(D_{i_k})\big)\subset \pi_{X_{k+1}\cap U_{i_k}}\big(\eta_{k+1}(B_{k+1})\big), \quad \forall i_k\in I_k, \tag{13}$$

and

$$\pi_{X_k}(\mathcal{F}_k) \subset_{\varepsilon_k} \eta_k(B_k).$$
 (14)

Note that (13) is equivalent to

$$\pi_{X_{k+1}\cap Y_k}\big(\psi_k(E_k)\big)\subset \pi_{X_{k+1}\cap Y_k}\big(\eta_{k+1}(B_{k+1})\big). \tag{15}$$

For the first step of induction, k = n, we choose  $\psi_n = \bigoplus_{i_n} \widetilde{\varphi}_{i_n}$  where  $\widetilde{\varphi}_{i_n} : C(U_{i_n}) \otimes D_{i_n} \to A(U_{i_n})$  are  $C(U_{i_n})$ -linear extensions of the original  $\varphi_{i_n}$ . Then  $B_n = E_n$  and  $\eta_n = \psi_n$ . Assume that  $\psi_n, \ldots, \psi_{k+1}$  were constructed and that they have the desired properties. We shall construct now  $\psi_k$ . Condition (14) formulated for k+1 becomes

$$\pi_{X_{k+1}}(\mathcal{F}_{k+1}) \subset_{\varepsilon_{k+1}} \eta_{k+1}(B_{k+1}).$$
 (16)

Since  $\varepsilon_{k+1} < \delta_{i_k}$ , by using (11) and (16) we obtain

$$\pi_{X_{k+1}\cap U_{i_k}}\left(\varphi_{i_k}(\mathcal{G}_{i_k})\right)\subset_{\delta_{i_k}}\pi_{X_{k+1}\cap U_{i_k}}\left(\eta_{k+1}(B_{k+1})\right),\quad\text{for all }i_k\in I_k.$$

Since  $\mathcal{F}_k \subseteq \mathcal{F}_{k+1}$  and  $\varepsilon_{k+1} < \varepsilon_k$ , condition (16) gives

$$\pi_{X_{k+1}}(\mathcal{F}_k) \subset_{\varepsilon_k} \eta_{k+1}(B_{k+1}). \tag{18}$$

Conditions (9), (17) and (18) enable us to apply Lemma 4.4 and perturb  $\widetilde{\varphi}_{i_k}$  to a \*-monomorphism  $\psi_{i_k}: C(U_{i_k}) \otimes D_{i_k} \to A(U_{i_k})$  satisfying (13) and (14) and such that

$$KK(\psi_{i_k}|_{D_{i_k}}) = KK(\varphi_{i_k}) \tag{19}$$

if the algebras in  $\mathcal{C}$  are assumed to be KK-stable. We set  $\psi_k = \bigoplus_{i_k} \psi_{i_k}$  and this completes the construction of  $(\psi_0, \dots, \psi_n)$ . Condition (14) for k = 0 gives  $\mathcal{F} \subset_{\varepsilon} \eta_0(B_0) = \eta(A(\psi_0, \dots, \psi_n))$ .

Thus  $(\psi_0, \ldots, \psi_n)$  satisfies the conclusion of the theorem. Finally let us note that it can happen that  $X_k = X$  for some k > 0. In this case  $\mathcal{F} \subset_{\varepsilon} A(\psi_k, \ldots, \psi_n)$  and for this reason we write  $n \leq \dim(X)$  in the statement of the theorem.  $\square$ 

**Proposition 4.7.** Let X be a finite dimensional compact metrizable space and let A be a separable continuous C(X)-algebra the fibers of which are stable Kirchberg algebras. Let D be a KK-semiprojective stable Kirchberg algebra and suppose that there exists  $\sigma \in KK(D, A)$  such that  $\sigma_x \in KK(D, A(x))^{-1}$  for all  $x \in X$ . For any finite subset  $\mathcal{F}$  of A and any  $\varepsilon > 0$  there is an n-fibered C-monomorphism  $(\psi_0, \ldots, \psi_n)$  into A such that  $n \leq \dim(X)$ ,  $C = \{D\}$ , and each component  $\psi_i : C(Y_i) \otimes D \to A(Y_i)$  satisfies  $KK(\psi_i) = \sigma_{Y_i}$ ,  $i = 0, \ldots, n$ . Moreover, if  $\eta : A(\psi_0, \ldots, \psi_n) \to A$  is the induced \*-monomorphism, then  $\mathcal{F} \subset_{\varepsilon} \eta(A(\psi_0, \ldots, \psi_n))$  and  $KK(\eta_x)$  is a KK-equivalence for each  $x \in X$ .

**Proof.** We repeat the proof of Theorem 4.6 while using only  $(\mathcal{F}_i, \varepsilon_i, \{D\})$ -approximations of A provided by the second part of Lemma 4.5. The outcome will be an n-fibered  $\{D\}$ -monomorphism  $(\psi_0, \ldots, \psi_n)$  into A such that  $\mathcal{F} \subset_{\varepsilon} \eta(A(\psi_0, \ldots, \psi_n))$ . Moreover we can arrange that  $KK(\psi_i) = \sigma_{Y_i}$  for all  $i = 0, \ldots, n$ , by (19), since  $KK(\varphi_{i_k}) = \sigma_{U_{i_k}}$  by Lemma 4.5. If  $x \in X$ , and  $i = \min\{k: x \in Y_k\}$ , then  $\eta_x \equiv (\psi_i)_x$ , and hence  $KK(\eta_x)$  is a KK-equivalence.  $\square$ 

Remark 4.8. Let us point out that we can strengthen the conclusion of Theorem 4.6 and Proposition 4.7 as follows. Fix a metric d for the topology of X. Then we may arrange that there is a closed cover  $\{Y'_0,\ldots,Y'_n\}$  of X and a number  $\ell>0$  such that  $\{x\colon d(x,Y'_i)\leqslant\ell\}\subset Y_i$  for  $i=0,\ldots,n$ . Indeed, when we choose the finite closed cover  $\mathcal{U}=(U_i)_{i\in I}$  of X in the proof of Theorem 4.6 which can be partitioned into n+1 subsets  $\mathcal{U}_0,\ldots,\mathcal{U}_n$  consisting of mutually disjoints elements, as given by [4, Lemma 3.2], and which refines all the covers  $\mathcal{U}(\alpha_0),\ldots,\mathcal{U}(\alpha_n)$  corresponding to  $\alpha_0,\ldots,\alpha_n$ , we may assume that  $\mathcal{U}$  also refines the covers given by the interiors of the elements of  $\mathcal{U}(\alpha_0),\ldots,\mathcal{U}(\alpha_n)$ . Since each  $U_i$  is compact and I is finite, there is  $\ell>0$  such that if  $V_i=\{x\colon d(x,U_i)\leqslant\ell\}$ , then the cover  $\mathcal{V}=(V_i)_{i\in I}$  still refines all of  $\mathcal{U}(\alpha_0),\ldots,\mathcal{U}(\alpha_n)$  and for each  $k=0,\ldots,n$ , the elements of  $\mathcal{V}_k=\{V_i\colon U_i\in\mathcal{U}_k\}$ , are still mutually disjoint. We shall use the cover  $\mathcal{V}$  rather than  $\mathcal{U}$  in the proof of the two theorems and observe that  $Y'_k\stackrel{def}{=}\bigcup_{i_k\in I_k}U_{i_k}\subset\bigcup_{i_k\in I_k}V_{i_k}=Y_k$  has the desired property. Finally let us note that if we define  $\psi'_i\colon E(Y'_i)\to A(Y'_i)$  by  $\psi'_i=\pi_{Y'_i}\psi_i$ , then  $(\psi'_0,\ldots,\psi'_n)$  is an n-fibered  $\mathcal{C}$ -monomorphism into A which satisfies the conclusion of Theorem 4.6 and Proposition 4.7 since  $\pi_{Y'_i}(\mathcal{F})\subset_{\mathcal{E}}\psi'_i(E_i)$  for all  $i=0,\ldots,n$  and  $X=\bigcup_{i=1}^n Y'_i$ .

#### 5. Representing C(X)-algebras as inductive limits

We have seen that Theorem 4.6 yields exhaustive sequences for certain C(X)-algebras. In this section we show how to pass from an exhaustive sequence to a nested exhaustive sequence using semiprojectivity. The remainder of the paper does not depend on this section.

**Proposition 5.1.** Let X, A and C be as in Theorem 4.6. Let  $(\psi_0, \ldots, \psi_n)$  be an n-fibered C-monomorphism into A with components  $\psi_i : E_i \to A(Y_i)$ . Let  $\mathcal{F}_i \subset E_i$ ,  $\mathcal{F} \subset A(\psi_0, \ldots, \psi_n)$  be finite sets and let  $\varepsilon > 0$ . Then there are finite sets  $\mathcal{G}_i \subset E_i$  and  $\delta_i > 0$ ,  $i = 0, \ldots, n$ , such that for any C(X)-subalgebra  $A' \subset A$  which satisfies  $\psi_i(\mathcal{G}_i) \subset \delta_i$   $A'(Y_i)$ ,  $i = 0, \ldots, n$ , there is an n-fibered C-monomorphism  $(\psi'_0, \ldots, \psi'_n)$  into A', with  $\psi'_i : E_i \to A'(Y_i)$  and such that (i)  $\|\psi_i(a) - \psi'_i(a)\| < \varepsilon$  for all  $a \in \mathcal{F}_i$  and all  $i \in \{0, \ldots, n\}$ , (ii)  $(\psi_j)_x^{-1}(\psi_i)_x = (\psi'_j)_x^{-1}(\psi'_j)_x$ 

for all  $x \in Y_i \cap Y_j$  and  $0 \le i \le j \le n$ . Moreover  $A(\psi_0, \dots, \psi_n) = A'(\psi'_0, \dots, \psi'_n)$  and the maps  $\eta : A(\psi_0, \dots, \psi_n) \to A$  and  $\eta' : A'(\psi'_0, \dots, \psi'_n) \to A'$  induced by  $(\psi_0, \dots, \psi_n)$  and  $(\psi'_0, \dots, \psi'_n)$  satisfy (iii)  $\|\eta(a) - \eta'(a)\| < \varepsilon$  for all  $a \in \mathcal{F}$ .

**Proof.** Let us observe that if we prove (i) and (ii) then (iii) will follow by enlarging the sets  $\mathcal{F}_i$  so that  $p_i(\mathcal{F}) \subset \mathcal{F}_i$ , where  $p_i: A(\psi_0, \dots, \psi_n) \to E_i$  are the coordinate maps. We proceed now with the proof of (i) and (ii) by making some simplifications. We may assume that  $E_0 = C(Y_0) \otimes D_0$  with  $D_0 \in \mathcal{C}$  since the perturbations corresponding to disjoint closed sets can be done independently of each other. Without any loss of generality, we may assume that  $\mathcal{F}_0 \subset D_0$  since we are working with morphisms on  $E_0$  which are  $C(Y_0)$ -linear. We also enlarge  $\mathcal{F}_0$  so that for each direct summand C of  $D_0$ ,  $\mathcal{F}_0$  contains an element c which is full in C and such that  $\|c\| \ge 2\varepsilon$ .

The proof is by induction on n. If n=0 the statement follows from Proposition 3.7 and Lemma 4.1. Assume now that the statement is true for n-1. Let  $E_i$ ,  $\psi_i$ , A, A',  $\mathcal{F}_i$ ,  $1 \le i \le n$  and  $\varepsilon$  be as in the statement. For  $0 \le i < j \le n$  let  $\eta_{j,i} : E_i(Y_i \cap Y_j) \to E_j(Y_i \cap Y_j)$  be the \*-homomorphism of  $C(Y_i \cap Y_j)$ -algebras defined fiberwise by  $(\eta_{j,i})_x = (\psi_j)_x^{-1}(\psi_i)_x$ .

Let  $\mathcal{G}_0$  and  $\delta_0$  be given by Proposition 3.8 applied to the C\*-algebra  $D_0$  for the input data  $\mathcal{F}_0$  and  $\varepsilon$ . For each  $1 \leq j \leq n$  choose a finite subset  $\mathcal{H}_j$  of  $E_j$  whose restriction to  $Y_j \cap Y_0$  contains  $\eta_{j,0}(\mathcal{G}_0)$ . Consider the sets  $\mathcal{F}'_j := \mathcal{F}_j \cup \mathcal{H}_j$ ,  $1 \leq j \leq n$  and the number  $\varepsilon' = \min\{\delta_0, \varepsilon\}$ . Let  $\mathcal{G}_1, \ldots, \mathcal{G}_n$  and  $\delta_1, \ldots, \delta_n$  be given by the inductive assumption for n-1 applied to  $A(X_1)$ ,  $A'(X_1), \psi_j, \mathcal{F}'_j, 1 \leq j \leq n$  and  $\varepsilon'$ , where  $X_1 = Y_1 \cup \cdots \cup Y_n$ .

We need to show that  $\mathcal{G}_0, \mathcal{G}_1, \ldots, \mathcal{G}_n$  and  $\delta_0, \delta_1, \ldots, \delta_n$  satisfy the statement. By the inductive step there exists an (n-1)-fibered  $\mathcal{C}$ -monomorphism  $(\psi'_1, \ldots, \psi'_n)$  into  $A'(X_1)$  with components  $\psi'_i : E_i \to A'(Y_i)$  such that

- (a)  $\|\psi_j(a) \psi_j'(a)\| < \varepsilon' = \min\{\delta_0, \varepsilon\}$  for all  $a \in \mathcal{F}_j \cup \mathcal{H}_j$  and all  $1 \leqslant j \leqslant n$ ,
- (b)  $(\psi_j)_x^{-1}(\psi_i)_x = (\psi_i')_x^{-1}(\psi_i')_x$  for all  $x \in Y_i \cap Y_j$  and  $1 \le i \le j \le n$ .

The condition (b) enables to define a \*-homomorphism  $\varphi: E_0 \to A'(Y_0 \cap X_1)$  with fiber maps  $\varphi_x = (\psi_j')_x (\psi_j^{-1})_x (\psi_0)_x$  for  $x \in Y_0 \cap Y_j$  and  $1 \leq j \leq n$ .

Let us observe that  $\psi_0: E_0 \to A(Y_0)$  is an approximate lifting of  $\varphi$ . More precisely we have  $\|\pi_{X_1 \cap Y_0}^{Y_0} \psi_0(a) - \varphi(a)\| < \delta_0$  for all  $a \in \mathcal{G}_0$ . Indeed, for  $x \in Y_0 \cap Y_j$ ,  $1 \le j \le n$  and  $a \in \mathcal{G}_0$  we have

$$\|(\psi_{0})_{x}(a(x)) - (\psi'_{j})_{x}(\psi_{j}^{-1})_{x}(\psi_{0})_{x}(a(x))\| = \|(\psi_{j})_{x}(\eta_{j,0})_{x}(a(x)) - (\psi'_{j})_{x}(\eta_{j,0})_{x}(a(x))\|$$

$$\leq \sup_{h \in \mathcal{H}_{j}} \|\psi_{j}(h) - \psi'_{j}(h)\| < \varepsilon' \leq \delta_{0}.$$

Since we also have  $\psi_0(\mathcal{G}_0) \subset_{\delta_0} A'(Y_0)$  by hypothesis, it follows from Proposition 3.8 that there exists  $\psi_0': D_0 \to A(Y_0)$  such that  $\|\psi_0'(a) - \psi_0(a)\| < \varepsilon$  for all  $a \in \mathcal{F}_0$  and  $\pi_{Y_0 \cap X_1}^{Y_0} \psi_0' = \varphi$ . By Lemma 4.1 each  $(\psi_0')_x$  is injective since each  $(\psi_0)_x$  is injective. The  $C(Y_0)$ -linear extension of  $\psi_0'$  to  $E_0$  satisfies  $(\psi_j)_x^{-1}(\psi_0)_x = (\psi_j')_x^{-1}(\psi_0')_x$  for all  $x \in Y_0 \cap Y_j$  and  $1 \leqslant j \leqslant n$  and this completes the proof of (ii). Condition (i) follows from (b).  $\square$ 

The following result gives an inductive limit representation for continuous C(X)-algebras whose fibers are inductive limits of finite direct sums of simple semiprojective C\*-algebras. For

example the fibers can be arbitrary AF-algebras or Kirchberg algebras which satisfy the UCT and whose  $K_1$ -groups are torsion free. Indeed, by [29, Prop. 8.4.13], these algebras are isomorphic to inductive limits of sequences of Kirchberg algebras  $(D_n)$  with finitely generated K-theory groups and torsion free  $K_1$ -groups. The algebras  $D_n$  are semiprojective by [33].

**Theorem 5.2.** Let C be a class consisting of finite direct sums of semiprojective simple C\*algebras. Let X be a finite dimensional compact metrizable space and let A be a separable continuous C(X)-algebra such that all its fibers admit exhaustive sequences consisting of  $C^*$ algebras isomorphic to C\*-algebras in C. Then A is isomorphic to the inductive limit of a sequence of continuous C(X)-algebras  $A_k$  such that  $cat_C(A_k) \leq dim(X)$ .

**Proof.** By Theorem 4.6 and Proposition 5.1 we find a sequence  $(\psi_0^{(k)}, \dots, \psi_n^{(k)})$  of *n*-fibered  $\mathcal{C}$ monomorphisms into A which induces \*-monomorphisms  $\eta^{(k)}: A_k = A(\psi_0^{(k)}, \dots, \psi_n^{(k)}) \to A$ with the following properties. There is a sequence of finite sets  $\mathcal{F}_k \subset A_k$  and a sequence of C(X)-linear \*-monomorphisms  $\mu_k: A_k \to A_{k+1}$  such that

- (i)  $\|\eta^{(k+1)}\mu_k(a) \eta^{(k)}(a)\| < 2^{-k}$  for all  $a \in \mathcal{F}_k$  and all  $k \ge 1$ ,
- (ii)  $\mu_k(\mathcal{F}_k) \subset \mathcal{F}_{k+1}$  for all  $k \geqslant 1$ , (iii)  $\bigcup_{j=k+1}^{\infty} (\mu_{j-1} \circ \cdots \circ \mu_k)^{-1}(\mathcal{F}_j)$  is dense in  $A_k$  and  $\bigcup_{j=k}^{\infty} \eta^{(j)}(\mathcal{F}_j)$  is dense in A for all  $k \geqslant 1$ .

Arguing as in the proof of [29, Prop. 2.3.2], one verifies that

$$\varphi_k(a) = \lim_{j \to \infty} \eta^{(j)} \circ (\mu_{j-1} \circ \cdots \circ \mu_k)(a)$$

defines a sequence of \*-monomorphisms  $\varphi_k: A_k \to A$  such that  $\varphi_{k+1}\mu_k = \varphi_k$  and the induced map  $\varphi : \underline{\lim}_{k} (A_{k}, \mu_{k}) \to A$  is an isomorphism of C(X)-algebras.

**Remark 5.3.** By similar arguments one proves a unital version of Theorem 5.2.

#### 6. When is a fibered product locally trivial

For C\*-algebras A, B we endow the space Hom(A, B) of \*-homomorphisms with the pointnorm topology. If X is a compact Hausdorff space, then  $\operatorname{Hom}(A, C(X) \otimes B)$  is homeomorphic to the space of continuous maps from X to Hom(A, B) endowed with the compact-open topology. We shall identify a \*-homomorphism  $\varphi \in \text{Hom}(A, C(X) \otimes B)$  with the corresponding continuous map  $X \to \operatorname{Hom}(A, B)$ ,  $x \mapsto \varphi_x$ ,  $\varphi_x(a) = \varphi(a)(x)$  for all  $x \in X$  and  $a \in A$ . Let D be a C\*-algebra and let A be a C(X)-algebra. If  $\alpha: D \to A$  is a \*-homomorphism, let us denote by  $\widetilde{\alpha}: C(X) \otimes D \to A$  its (unique) C(X)-linear extension and write  $\widetilde{\alpha} \in \operatorname{Hom}_{C(X)}(C(X) \otimes D, A)$ . For  $C^*$ -algebras D, B we shall make without further comment the following identifications

$$\operatorname{Hom}_{C(X)}\big(C(X)\otimes D,C(X)\otimes B\big)\equiv\operatorname{Hom}\big(D,C(X)\otimes B\big)\equiv C\big(X,\operatorname{Hom}(D,B)\big).$$

For a C\*-algebra D we denote by End(D) the set of full (and unital if D is unital) \*endomorphisms of D and by  $\operatorname{End}(D)^0$  the path component of  $\operatorname{id}_D$  in  $\operatorname{End}(D)$ . Let us consider

$$\operatorname{End}(D)^* = \left\{ \gamma \in \operatorname{End}(D) \colon KK(\gamma) \in KK(D, D)^{-1} \right\}.$$

**Proposition 6.1.** Let X be a compact metrizable space and let D be a KK-semiprojective K-irchberg algebra. Let  $\alpha: D \to C(X) \otimes D$  be a full (and unital, if D is unital) \*-homomorphism such that  $KK(\alpha_x) \in KK(D,D)^{-1}$  for all  $x \in X$ . Then there is a full \*-homomorphism  $\Phi: D \to C(X \times [0,1]) \otimes D$  such that  $\Phi_{(x,0)} = \alpha_x$  and  $\Phi_{(x,t)} \in Aut(D)$  for all  $x \in X$  and  $t \in (0,1]$ . Moreover, if  $\Phi_1: D \to C(X) \otimes D$  is defined by  $\Phi_1(d)(x) = \Phi_{(x,1)}(d)$ , for all  $d \in D$  and  $x \in X$ , then  $\alpha \approx_{uh} \Phi_1$ .

**Proof.** Since X is a metrizable compact space, X is homeomorphic to the projective limit of a sequence of finite simplicial complexes  $(X_i)$  by [13, Thm. 10.1, p. 284]. Since D is KKsemiprojective,  $KK(D, \lim_{X \to \infty} C(X_i) \otimes D) = KK(D, C(X) \otimes D)$  by Theorem 3.12. By Theorem 3.1, there is i and a full (and unital if D is unital) \*-homomorphism  $\varphi: D \to C(X_i) \otimes D$  whose KKclass maps to  $KK(\alpha) \in KK(D, C(X) \otimes D)$ . To summarize, we have found a finite simplicial complex Y, a continuous map  $h: X \to Y$  and a continuous map  $y \mapsto \varphi_y \in \text{End}(D)$ , defined on Y, such that the full (and unital if D is unital) \*-homomorphism  $h^*\varphi:D\to C(X)\otimes D$ corresponding to the continuous map  $x \mapsto \varphi_{h(x)}$  satisfies  $KK(h^*\varphi) = KK(\alpha)$ . We may arrange that h(X) intersects all the path components of Y by dropping the path components which are not intersected. Since  $\alpha_x \in \text{End}(D)^*$  by hypothesis, and since  $KK(\alpha_x) = KK(\varphi_{h(x)})$ , we infer that  $\varphi_y \in \operatorname{End}(D)^*$  for all  $y \in Y$ . We shall find a continuous map  $y \mapsto \psi_y \in \operatorname{End}(D)^*$  defined on Y, such that the maps  $y \mapsto \psi_y \varphi_y$  and  $y \mapsto \varphi_y \psi_y$  are homotopic to the constant map  $\iota$  that takes Y to  $id_D$ . It is clear that it suffices to deal separately with each path component of Y, so that for this part of the proof we may assume that Y is connected. Fix a point  $z \in Y$ . By [29, Thm. 8.4.1] there is  $v \in Aut(D)$  such that  $KK(v^{-1}) = KK(\varphi_{\tau})$  and hence  $KK(v\varphi_{\tau}) = KK(\mathrm{id}_D)$ . By Theorem 3.1, there is a unitary  $u \in M(D)$  such that  $uv\varphi_z(-)u^*$  is homotopic to  $\mathrm{id}_D$ . Let us set  $\theta = uv(-)u^* \in Aut(D)$  and observe that  $\theta \varphi_z \in End(D)^0$ . Since Y is path connected, it follows that the entire image of the map  $y \mapsto \theta \varphi_y$  is contained in End $(D)^0$ . Since End $(D)^0$  is a path connected H-space with unit element, it follows by [38, Thm. 2.4, p. 462] that the homotopy classes [Y, End(D) $^0$ ] (with no condition on basepoints, since the action of the fundamental group  $\pi_1(\operatorname{End}(D)^0, \operatorname{id}_D)$  is trivial by [38, 3.6, p. 166]) form a group under the natural multiplication. Therefore we find  $y \mapsto \psi'_{\nu} \in \text{End}(D)^0$  such that  $y \mapsto \psi'_{\nu}\theta\varphi_y$  and  $y \mapsto \theta\varphi_y\psi'_{\nu}$  are homotopic to  $\iota$ .

It follows that  $y \mapsto \psi_y \stackrel{def}{=} \psi_y' \theta$  is the homotopic inverse of  $y \mapsto \varphi_y$  in  $[Y, \operatorname{End}(D)^*]$ . Composing with h we obtain that the maps  $x \mapsto \varphi_{h(x)} \psi_{h(x)}$  and  $x \mapsto \psi_{h(x)} \varphi_{h(x)}$  are homotopic to the constant map that takes X to  $\operatorname{id}_D$ . By the homotopy invariance of KK-theory we obtain that

$$KK(\widetilde{h^*\varphi}h^*\psi) = KK(\widetilde{h^*\psi}h^*\varphi) = KK(\iota_D),$$

where  $\widetilde{h^*\varphi}$  and  $\widetilde{h^*\psi}$  denote the C(X)-linear extensions of the corresponding maps and  $\iota_D: D \to C(X) \otimes D$  is defined by  $\iota_D(d) = 1_{C(X)} \otimes d$  for all  $d \in D$ . Let us recall that  $KK(h^*\varphi) = KK(\alpha)$  and hence  $KK(\widetilde{h^*\varphi}) = KK(\widetilde{\alpha})$ . If we set  $\Psi = h^*\psi$ , then

$$KK(\widetilde{\alpha}\Psi) = KK(\widetilde{\Psi}\alpha) = KK(\iota_D).$$

By Theorem 3.1  $\widetilde{\alpha}\Psi \approx_u \iota_D$  and  $\widetilde{\Psi}\alpha \approx_u \iota_D$ , and hence  $\widetilde{\alpha}\widetilde{\Psi} \approx_u \operatorname{id}_{C(X)\otimes D}$  and  $\widetilde{\Psi}\widetilde{\alpha} \approx_u \operatorname{id}_{C(X)\otimes D}$ . By [29, Cor. 2.3.4], there is an isomorphism  $\Gamma: C(X)\otimes D\to C(X)\otimes D$  such that  $\Gamma\approx_u\widetilde{\alpha}$ . In particular  $\Gamma$  is C(X)-linear and  $\Gamma_X\in\operatorname{Aut}(D)$  for all  $X\in X$ . Replacing  $\Gamma$  by  $U\Gamma(\cdot)U^*$  for some unitary  $u \in M(C(X) \otimes D)$  we can arrange that  $\Gamma|_D$  is arbitrarily close to  $\alpha$ . Therefore  $KK(\Gamma|_D) = KK(\alpha)$  since D is KK-stable. By Theorem 3.1 there is a continuous map  $(0,1] \to U(M(C(X) \otimes D))$ ,  $t \mapsto u_t$ , with the property that

$$\lim_{t\to 0} \|u_t \Gamma(a) u_t^* - \alpha(a)\| = 0, \quad \text{for all } a \in D.$$

Therefore the equation

$$\Phi_{(x,t)} = \begin{cases} \alpha_x, & \text{if } t = 0, \\ u_t(x) \Gamma_x u_t(x)^*, & \text{if } t \in (0, 1], \end{cases}$$

defines a continuous map  $\Phi: X \times [0,1] \to \operatorname{End}(D)^*$  which extends  $\alpha$  and such that  $\Phi(X \times (0,1]) \subset \operatorname{Aut}(D)$ . Since  $\alpha$  is homotopic to  $\Phi_1$ , we have that  $\alpha \approx_{uh} \Phi_1$  by Theorem 3.1.  $\square$ 

**Proposition 6.2.** Let X be a compact metrizable space and let D be a KK-semiprojective K irchberg algebra. Let Y be a closed subset of X. Assume that a map  $\gamma: Y \to \operatorname{End}(D)^*$  extends to a continuous map  $\alpha: X \to \operatorname{End}(D)^*$ . Then there is a continuous extension  $\eta: X \to \operatorname{End}(D)^*$  of  $\gamma$ , such that  $\eta(X \setminus Y) \subset \operatorname{Aut}(D)$ .

**Proof.** Since the map  $x \to \alpha_x$  takes values in  $\operatorname{End}(D)^*$ , by Proposition 6.1 there exists a continuous map  $\Phi: X \times [0,1] \to \operatorname{End}(D)^*$  which extends  $\alpha$  and such that  $\Phi(X \times (0,1]) \subset \operatorname{Aut}(D)$ . Let d be a metric for the topology of X such that  $\operatorname{diam}(X) \leq 1$ . The equation  $\eta(x) = \Phi(x,d(x,Y))$  defines a map on X that satisfies the conclusion of the proposition.  $\square$ 

**Lemma 6.3.** Let X be a compact metrizable space and let D be a KK-semiprojective K-irchberg algebra. Let Y be a closed subset of X. Let  $\alpha: Y \times [0,1] \cup X \times \{0\} \to \operatorname{End}(D)$  be a continuous map such that  $\alpha_{(x,0)} \in \operatorname{End}(D)^*$  for all  $x \in X$ . Suppose that there is an open set V in X which contains Y and such that  $\alpha$  extends to a continuous map  $\alpha_V: V \times [0,1] \cup X \times \{0\} \to \operatorname{End}(D)$ . Then there is  $\eta: X \times [0,1] \to \operatorname{End}(D)^*$  such that  $\eta$  extends  $\alpha$  and  $\eta_{(x,t)} \in \operatorname{Aut}(D)$  for all  $x \in X \setminus Y$  and  $t \in (0,1]$ .

**Proof.** By Proposition 6.2 it suffices to find a continuous map  $\widehat{\alpha}: X \times [0,1] \to \operatorname{End}(D)^*$  which extends  $\alpha$ . Fix a metric d for the topology of X and define  $\lambda: X \to [0,1]$  by  $\lambda(x) = d(x,X \setminus V)(d(x,X \setminus V) + d(x,Y))^{-1}$ . Let us define  $\widehat{\alpha}: X \times [0,1] \to \operatorname{End}(D)$  by  $\widehat{\alpha}_{(x,t)} = \alpha_V(x,\lambda(x)t)$  and observe that  $\widehat{\alpha}$  extends  $\alpha$ . Finally, since  $\widehat{\alpha}_{(x,t)}$  is homotopic to  $\widehat{\alpha}_{(x,0)} = \alpha_{(x,0)}$ , we conclude that the image of  $\widehat{\alpha}$  in contained in  $\operatorname{End}(D)^*$ .  $\square$ 

**Proposition 6.4.** Let X be a compact metrizable space and let D be a KK-semiprojective stable Kirchberg algebra. Let A be a separable C(X)-algebra which is locally isomorphic to  $C(X) \otimes D$ . Suppose that there is  $\sigma \in KK(D,A)$  such that  $\sigma_X \in KK(D,A(x))^{-1}$  for all  $x \in X$ . Then there is an isomorphism of C(X)-algebras  $\psi : C(X) \otimes D \to A$  such that  $KK(\psi|_D) = \sigma$ .

**Proof.** Since X is compact and A is locally trivial it follows that  $\operatorname{cat}_{\{D\}}(A) < \infty$ . By Lemma 2.9,  $A \cong pAp \otimes \mathcal{O}_{\infty} \otimes \mathcal{K}$  for some projection  $p \in A$ . By Theorem 3.1, there is a full \*-homomorphism  $\varphi : D \to A$  such that  $KK(\varphi) = \sigma$ . We shall construct an isomorphism of C(X)-algebras  $\psi : C(X) \otimes D \to A$  such that  $\psi$  is homotopic to  $\widetilde{\varphi}$ , the C(X)-linear extension

of  $\varphi$ . Moreover the homotopy  $(H_t)_{t \in [0,1]}$  will have the property that  $H_{(x,t)}: D \to A(x)$  is an isomorphism for all  $x \in X$  and t > 0. We prove this by induction on numbers n with the property that there are two closed covers of  $X, W_1, \ldots, W_n$  and  $Y_1, \ldots, Y_n$  such that  $Y_i$  contained in the interior of  $W_i$  and  $A(W_i) \cong C(W_i) \otimes D$  for  $1 \le i \le n$ . First we observe that the case n = 1 follows from Proposition 6.2. Let us now pass from n-1 to n. Given two covers as above, there is yet another closed cover  $V_1, \ldots, V_n$  of X such that  $V_i$  is a neighborhood of  $Y_i$  and  $W_i$  is a neighborhood. borhood of  $V_i$  for all  $1 \le i \le n$ . Set  $Y = \bigcup_{i=1}^{n-1} Y_i$ ,  $V = \bigcup_{i=1}^{n-1} V_i$  and  $W = \bigcup_{i=1}^{n-1} W_i$ . By the inductive hypothesis applied to A(V), and the covers  $V_1, \ldots, V_{n-1}$  and  $W_1 \cap V, \ldots, W_{n-1} \cap V$ there is a homotopy  $h: D \to A(V) \otimes C[0,1]$  such that  $h_{(x,0)} = \varphi_x$  and  $h_{(x,t)}: D \to A(x)$  is an isomorphism for all  $(x, t) \in V \times (0, 1]$ . Fix a trivialization  $\nu : A(Y_{n+1}) \to C(Y_{n+1}) \otimes D$ . Define a continuous map  $\alpha: (V \cap Y_{n+1}) \times [0,1] \cup Y_{n+1} \times \{0\} \to \operatorname{End}(D)$  by setting  $\alpha_{(x,t)} = \nu_x h_{(x,t)}$ if  $(x,t) \in (V \cap Y_{n+1}) \times [0,1]$  and  $\alpha_{(x,0)} = \nu_x \varphi_x$  if  $x \in Y_{n+1}$ . Since  $V \cap Y_{n+1}$  is a neighborhood of  $Y \cap Y_{n+1}$  in  $Y_{n+1}$  and since  $v_x \varphi_x \in \text{End}(D)^*$  for all  $x \in Y_{n+1}$ , by Lemma 6.3 there is a continuous map  $\eta: Y_{n+1} \times [0,1] \to \operatorname{End}(D)^*$  which extends the restriction of  $\alpha$  to  $(Y \cap Y_{n+1}) \times [0, 1] \cup Y_{n+1} \times \{0\}$ . We conclude the construction of the desired homotopy by defining  $H: D \to A(X) \otimes C[0, 1]$  by  $H_{(x,t)} = h_{(x,t)}$  for  $(x, t) \in Y \times [0, 1]$  and  $H_{(x,t)} = v_x^{-1} \eta_{(x,t)}$  for  $(x,t) \in Y_{n+1} \times [0,1].$ 

**Lemma 6.5.** Let D be a KK-semiprojective stable Kirchberg algebra. Let X be a compact metrizable space and Y, Z be closed subsets of X such that  $X = Y \cup Z$ . Suppose that  $\gamma: D \to C(Y \cap Z) \otimes D$  is a full \*-homomorphism which admits a lifting to a full \*-homomorphism  $\alpha: D \to C(Y) \otimes D$  such that  $\alpha_x \in \operatorname{End}(D)^*$  for all  $x \in Y$ . Then the pullback  $C(Y) \otimes D \oplus_{\pi_{Y \cap Z}, \widetilde{\gamma}_{\pi_{Y \cap Z}}} C(Z) \otimes D$  is isomorphic to  $C(X) \otimes D$ .

**Proof.** By Proposition 6.2 there is a \*-homomorphism  $\eta: D \to C(Y) \otimes D$  such that  $\eta_x = \gamma_x$  for  $x \in Y \cap Z$  and such that  $\eta_x \in \operatorname{Aut}(D)$  for  $x \in Y \setminus Z$ . Using the short five-lemma one checks immediately that the triplet  $(\widetilde{\eta}, \widetilde{\gamma}, \operatorname{id}_{C(Z) \otimes D})$  defines a C(X)-linear isomorphism:

$$C(X) \otimes D = C(Y) \otimes D \oplus_{\pi_{Y \cap Z}, \pi_{Y \cap Z}} C(Z) \otimes D \to C(Y) \otimes D \oplus_{\pi_{Y \cap Z}, \widetilde{\gamma} \pi_{Y \cap Z}} C(Z) \otimes D.$$

**Lemma 6.6.** Let D be a KK-semiprojective stable Kirchberg algebra. Let Y, Z and Z' be closed subsets of a compact metrizable space X such that Z' is a neighborhood of Z and  $X = Y \cup Z$ . Let B be a C(Y)-algebra locally isomorphic to  $C(Y) \otimes D$  and let E be a C(Z')-algebra locally isomorphic to  $C(Z') \otimes D$ . Let  $\alpha : E(Y \cap Z') \to B(Y \cap Z')$  be a \*-monomorphism of  $C(Y \cap Z')$ -algebras such that  $KK(\alpha_x) \in KK(E(x), B(x))^{-1}$  for all  $x \in Y \cap Z'$ . If  $\gamma = \alpha_{Y \cap Z}$ , then  $B(Y) \oplus_{\pi_{Y \cap Z}, \gamma \pi_{Y \cap Z}} E(Z)$  is locally isomorphic to  $C(X) \otimes D$ .

**Proof.** Since we are dealing with a local property, we may assume that  $B = C(Y) \otimes D$  and  $E = C(Z') \otimes D$ . To simplify notation we let  $\pi$  stand for both  $\pi_{Y \cap Z}^Y$  and  $\pi_{Y \cap Z}^Z$  in the sequel. Let us denote by H the C(X)-algebra  $C(Y) \otimes D \oplus_{\pi, \gamma\pi} C(Z) \otimes D$ . We must show that H is locally trivial. Let  $x \in X$ . If  $x \notin Z$ , then there is a closed neighborhood V of X which does not intersect X, and hence the restriction of X to X is isomorphic to X is a closed neighborhood of X in X and the restriction of X is isomorphic to X is isomorphic to X is a closed neighborhood of X in X and the restriction of X is isomorphic to X is isomorphic.

**Proposition 6.7.** Let X, A, D and  $\sigma$  be as in Proposition 4.7. For any finite subset  $\mathcal{F}$  of A and any  $\varepsilon > 0$  there is a C(X)-algebra B which is locally isomorphic to  $C(X) \otimes D$  and there exists a C(X)-linear \*-monomorphism  $\eta : B \to A$  such that  $\mathcal{F} \subset_{\varepsilon} \eta(B)$  and  $KK(\eta_X) \in KK(B(X), A(X))^{-1}$  for all  $X \in X$ .

**Proof.** Let  $\psi_k : E_k = C(Y_k) \otimes D \to A(Y_k)$ ,  $k = 0, \ldots, n$ , be as in the conclusion of Proposition 4.7, strengthen as in Remark 4.8. Therefore we may assume that there is another n-fibered  $\{D\}$ -monomorphism  $(\psi'_0, \ldots, \psi'_n)$  into A such that  $\psi'_k : C(Y'_k) \otimes D \to A(Y'_k)$ ,  $Y'_k$  is a closed neighborhood of  $Y_i$ , and  $\pi_{Y_k} \psi'_k = \psi_k$ ,  $k = 0, \ldots, n$ . Let  $X_k$ ,  $B_k$ ,  $\eta_k$  and  $\gamma_k$  be as in Definition 2.8.  $B_0$  and  $\eta_0$  satisfy the conclusion of the proposition, except that we need to prove that  $B_0$  is locally isomorphic to  $C(X) \otimes D$ . We prove by induction on decreasing k that the  $C(X_k)$ -algebras  $B_k$  are locally trivial. Indeed  $B_n = C(X_n) \otimes D$  and assuming that  $B_k$  is locally trivial, it follows by Lemma 6.6 that  $B_{k-1}$  is locally trivial, since by (5)

$$B_{k-1} \cong B_k \oplus_{\pi \eta_k, \pi \psi_{k-1}} E_{k-1} \cong B_k \oplus_{\pi, \gamma_k \pi} E_{k-1} \quad (\pi = \pi_{X_k \cap Y_{k-1}})$$

and  $\gamma_k: E_{k-1}(X_k \cap Y_{k-1}) \to B_k(X_k \cap Y_{k-1}), \ (\gamma_k)_x = (\eta_k)_x^{-1}(\psi_{k-1})_x$ , extends to a \*-monomorphism  $\alpha: E_{k-1}(X_k \cap Y_{k-1}') \to B_k(X_k \cap Y_{k-1}'), \ \alpha_x = (\eta_k)_x^{-1}(\psi_{k-1}')_x$  and  $KK(\alpha_x)$  is a KK-equivalence since both  $KK((\eta_k)_x)$  and  $KK((\psi_{k-1})_x)$  are KK-equivalences.  $\square$ 

# 7. When is a C(X)-algebra locally trivial

In this section we prove Theorems 1.1–1.5 and some of their consequences.

#### 7.1. Proof of Theorem 1.2

**Proof.** Let X denote the primitive spectrum of A. Then A is a continuous C(X)-algebra and its fibers are stable Kirchberg algebras (see [5, 2.2.2]). Since A is separable, X is metrizable by Lemma 2.2. By Proposition 6.7 there is a sequence of C(X)-algebras  $(A_k)_{k=1}^{\infty}$  locally isomorphic to  $C(X) \otimes D$  and a sequence of C(X)-linear \*-monomorphisms  $(\eta_k : A_k \to A)_{k=1}^{\infty}$ , such that  $KK(\eta_k)_x$  is a KK-equivalence for each  $x \in X$  and  $(\eta_k(A_k))_{k=1}^{\infty}$  is an exhaustive sequence of C(X)-subalgebras of A. Since D is weakly semiprojective and KK-stable, after passing to a subsequence of  $(A_k)$  if necessary, we find a sequence  $(\sigma_k)_{k=1}^{\infty}$ ,  $\sigma_k \in KK(D, A_k)$  such that  $KK(\eta_k)\sigma_k = \sigma$  for all  $k \ge 1$ . Since both  $KK(\eta_k)_x$  and  $\sigma_x$  are KK-equivalences, we deduce that  $(\sigma_k)_x \in KK(D, A_k(x))^{-1}$  for all  $x \in X$ . By Proposition 6.4, for each  $k \ge 1$  there is an isomorphism of C(X)-algebras  $\varphi_k : C(X) \otimes D \to A_k$  such that  $KK(\varphi_k) = \sigma_k$ . Therefore if we set  $\theta_k = \eta_k \varphi_k$ , then  $\theta_k$  is a C(X)-linear \*-monomorphism from  $B \stackrel{def}{=} C(X) \otimes D$  to A such that  $KK(\theta_k) = \sigma$  and  $(\theta_k(B))_{k=1}^{\infty}$  is an exhaustive sequence of C(X)-subalgebras of A. Using again the weak semiprojectivity and the KK-stability of D, and Lemma 4.1, after passing to a subsequence of  $(\theta_k)_{k=1}^{\infty}$ , we construct a sequence of finite sets  $\mathcal{F}_k \subset B$  and a sequence of C(X)-linear \*-monomorphisms  $\mu_k : B \to B$  such that

- (i)  $KK(\theta_{k+1}\mu_k) = KK(\theta_k)$  for all  $k \ge 1$ ,
- (ii)  $\|\theta_{k+1}\mu_k(a) \theta_k(a)\| < 2^{-k}$  for all  $a \in \mathcal{F}_k$  and all  $k \geqslant 1$ ,
- (iii)  $\mu_k(\mathcal{F}_k) \subset \mathcal{F}_{k+1}$  for all  $k \ge 1$ ,
- (iv)  $\bigcup_{i=k+1}^{\infty} (\mu_{j-1} \circ \cdots \circ \mu_k)^{-1}(\mathcal{F}_j)$  is dense in B and  $\bigcup_{i=k}^{\infty} \theta_j(\mathcal{F}_j)$  is dense in A for all  $k \ge 1$ .

Arguing as in the proof of [29, Prop. 2.3.2], one verifies that

$$\Delta_k(a) = \lim_{j \to \infty} \theta_j \circ (\mu_{j-1} \circ \cdots \circ \mu_k)(a)$$

defines a sequence of \*-monomorphisms  $\Delta_k: B \to A$  such that  $\Delta_{k+1}\mu_k = \Delta_k$  and the induced map  $\Delta: \varinjlim_k(B, \mu_k) \to A$  is an isomorphism of C(X)-algebras. Let us show that  $\varinjlim_k(B, \mu_k)$  is isomorphic to B. To this purpose, in view of Elliott's intertwining argument, it suffices to show that each map  $\mu_k$  is approximately unitarily equivalent to a C(X)-linear automorphism of B. Since  $KK(\theta_k) = \sigma$ , we deduce from (i) that  $KK((\mu_k)_x) = KK(\operatorname{id}_D)$  for all  $x \in X$ . By Proposition 6.1, this property implies that each map  $\mu_k$  is approximately unitarily equivalent to a C(X)-linear automorphism of B. Therefore there is an isomorphism of C(X)-algebras  $\Delta: B \to A$ . Let us show that we can arrange that  $KK(\Delta|_D) = \sigma$ . By Theorem 3.1, there is a full \*-homomorphism  $\alpha: D \to B$  such that  $KK(\alpha) = KK(\Delta^{-1})\sigma$ . Since  $KK(\Delta_x^{-1})\sigma_x \in KK(D,D)^{-1}$ , by Proposition 6.1 there is  $\Phi_1: D \to C(X) \otimes D$  such that  $\widetilde{\Phi}_1 \in \operatorname{Aut}_{C(X)}(B)$  and  $KK(\Phi_1) = KK(\Delta^{-1})\sigma$ . Then  $\Phi = \Delta\widetilde{\Phi}_1: B \to A$  is an isomorphism such that  $KK(\Phi|_D) = KK(\Delta\Phi_1) = \sigma$ .  $\square$ 

Dixmier and Douady [12] proved that a continuous field with fibers K over a finite dimensional locally compact Hausdorff space is locally trivial if and only it verifies Fell's condition, i.e. for each  $x_0 \in X$  there is a continuous section a of the field such that a(x) is a rank one projection for each x in a neighborhood of  $x_0$ . We have an analogous result:

**Corollary 7.1.** Let A be a separable  $C^*$ -algebra whose primitive spectrum X is Hausdorff and of finite dimension. Suppose that for each  $x \in X$ , A(x) is KK-semiprojective, nuclear, purely infinite and stable. Then A is locally trivial if and only if for each  $x \in X$  there exist a closed neighborhood V of x, a Kirchberg algebra D and  $\sigma \in KK(D, A(V))$  such that  $\sigma_v \in KK(D, A(v))^{-1}$  for each  $v \in V$ .

**Proof.** One applies Theorem 1.2 for  $D \otimes \mathcal{K}$  and A(V).  $\square$ 

**Proposition 7.2.** Let  $\psi$  be a full endomorphism of a Kirchberg algebra D. If D is unital we assume that  $\psi(1) = 1$  as well. Then the continuous C[0, 1]-algebra  $E = \{ f \in C[0, 1] \otimes D \colon f(0) \in \psi(D) \}$  is locally trivial if and only if  $\psi$  is homotopic to an automorphism of D.

**Proof.** Suppose that E is trivial on some neighborhood of 0. Thus there is  $s \in (0, 1]$  and an isomorphism  $\theta: C[0, s] \otimes D \xrightarrow{\simeq} E[0, s]$ . Since  $E[0, s] \subset C[0, s] \otimes D$ , there is a continuous path  $(\theta_t)_{t \in [0, s]}$  in  $\operatorname{End}(D)$  such that  $\theta_t \in \operatorname{Aut}(D)$  for  $0 < t \leqslant s$  and  $\theta_0(D) = \psi(D)$ . Set  $\beta = \theta_0^{-1} \psi \in \operatorname{Aut}(D)$ . Then  $\psi$  is homotopic to an automorphism via the path  $(\theta_t \beta)_{t \in [0, s]}$ . Conversely, if  $\psi$  is homotopic to an automorphism  $\alpha$ , then by Theorem 3.1 there is a continuous path  $(u_t)_{t \in [0, 1]}$  of unitaries in  $D^+$  such that  $\lim_{t \to 0} \|\psi(d) - u_t \alpha(d) u_t^*\| = 0$  for all  $d \in D$ . The path  $(\theta_t)_{t \in [0, 1]}$  defined by  $\theta_0 = \psi$  and  $\theta_t = u_t \alpha u_t^*$  for  $t \in (0, 1]$  induces a C[0, 1]-linear \*-endomorphism of  $C[0, 1] \otimes D$  which maps injectively  $C[0, 1] \otimes D$  onto E.  $\square$ 

#### 7.2. Proof of Theorem 1.3

**Proof.** For the first part we apply Theorem 1.2 for  $D = \mathcal{O}_2 \otimes \mathcal{K}$  and  $\sigma = 0$ . For the second part we assert that if D is a Kirchberg such that all continuous C[0, 1]-algebras with fibers isomorphic

to D are locally trivial then D is stable and KK(D,D)=0. Thus D is KK-equivalent to  $\mathcal{O}_2$  and hence that  $D\cong\mathcal{O}_2\otimes\mathcal{K}$  by [29, Thm. 8.4.1]. The Kirchberg algebra D is either unital or stable [29, Prop. 4.1.3]. Let  $\psi:D\to D$  be a \*-monomorphism such that  $KK(\psi)=0$  and such that  $\psi(1_D)<1_D$  if D is unital. By Proposition 7.2  $\psi$  is homotopic to an automorphism of  $\theta$  of D. Therefore D must be nonunital (and hence stable), since otherwise  $1_D$  would be homotopic to its proper subprojection  $\psi(1_D)$ . Moreover  $KK(\theta)=KK(\psi)=0$  and hence KK(D,D)=0 since  $\theta$  is an automorphism.  $\square$ 

We turn now to unital C(X)-algebras.

**Theorem 7.3.** Let A be a separable unital C(X)-algebra over a finite dimensional compact Hausdorff space X. Suppose that each fiber A(x) is nuclear simple and purely infinite. Then A is isomorphic to  $C(X) \otimes D$ , for some KK-semiprojective unital Kirchberg algebra D, if and only if there is  $\sigma \in KK(D,A)$  such that  $K_0(\sigma)[1_D] = [1_A]$  and  $\sigma_x \in KK(D,A(x))^{-1}$  for all  $x \in X$ . For any such  $\sigma$  there is an isomorphism of C(X)-algebras  $\Phi : C(X) \otimes D \to A$  such that  $KK(\Phi|_D) = \sigma$ .

**Proof.** We verify the nontrivial implication. X is metrizable by Lemma 2.2. A is a continuous C(X)-algebra by Lemma 2.3. By Theorem 1.2, there is an isomorphism  $\Phi: C(X) \otimes D \otimes \mathcal{K} \to A \otimes \mathcal{K}$  such that  $KK(\Phi) = \sigma$ . Since  $K_0(\sigma)[1_D] = [1_A]$ , and since  $A \otimes \mathcal{K}$  contains a full properly infinite projection, we may arrange that  $\Phi(1_{C(X)\otimes D} \otimes e_{11}) = 1_A \otimes e_{11}$  after conjugating  $\Phi$  by some unitary  $u \in M(A \otimes \mathcal{K})$ . Then  $\varphi = \Phi|_{C(X)\otimes D\otimes e_{11}}$  satisfies the conclusion of the theorem.  $\square$ 

#### 7.3. Proof of Theorem 1.4

**Proof.** Let D be a KK-semiprojective unital Kirchberg algebra D such that every unital \*-endomorphism of D is a KK-equivalence. Suppose that A is a separable unital C(X)-algebra over a finite dimensional compact Hausdorff space the fibers of which are isomorphic to D. We shall prove that A is locally trivial. By Theorem 7.3, it suffices to show that each point  $x_0 \in X$  has a closed neighborhood V for which there is  $\sigma \in KK(D, A(V))$  such that  $K_0(\sigma)[1_D] = [1_{A(V)}]$  and  $\sigma_x \in KK(D, A(x))^{-1}$  for all  $x \in V$ .

Let  $(V_n)_{n=1}^{\infty}$  be a decreasing sequence of closed neighborhoods of  $x_0$  whose intersection is  $\{x_0\}$ . Then  $A(x_0) \cong \varinjlim A(V_n)$ . By assumption, there is an isomorphism  $\eta: D \to A(x_0)$ . Since D is KK-semiprojective, there is  $m \geqslant 1$  such that  $KK(\eta)$  lifts to some  $\sigma \in KK(D, A(V_m))$  such that  $K_0(\sigma)[1_D] = [1_{A(V_m)}]$ . Let  $x \in V_m$ . By assumption, there is an isomorphism  $\varphi: A(x) \to D$ . The  $K_0$ -morphism induced by  $KK(\varphi)\sigma_x$  maps  $[1_D]$  to itself. By Theorem 3.1 there is a unital \*-homomorphism  $\psi: D \to D$  such that  $KK(\psi) = KK(\varphi)\sigma_x$ . By assumption we must have  $KK(\psi) \in KK(D, D)^{-1}$  and hence  $\sigma_x \in KK(D, A(x))^{-1}$  since  $\varphi$  is an isomorphism. Therefore  $A(V_m) \cong C(V_m) \otimes D$  by Theorem 7.3.

Conversely, let us assume that all separable unital continuous C[0, 1]-algebras with fibers isomorphic to D are locally trivial. Let  $\psi$  be any unital \*-endomorphism of D. By Proposition 7.2  $\psi$  is homotopic to an automorphism of D and hence  $KK(\psi)$  is invertible.  $\square$ 

#### 7.4. Proof of Theorem 1.1

**Proof.** Let A be as in Theorem 1.1 and let  $n \in \{2, 3, ...\} \cup \{\infty\}$ . It is known that  $\mathcal{O}_n$  satisfies the UCT. Moreover  $K_0(\mathcal{O}_n)$  is generated by  $[1_{\mathcal{O}_n}]$  and  $K_1(\mathcal{O}_n) = 0$ . Therefore any unital \*-

endomorphism of  $\mathcal{O}_n$  is a KK-equivalence. It follows that A is locally trivial by Theorem 1.4. Suppose now that n=2. Since  $KK(\mathcal{O}_2,\mathcal{O}_2)=KK(\mathcal{O}_2,A)=0$ , we may apply Theorem 1.4 with  $\sigma=0$  and obtain that  $A\cong C(X)\otimes \mathcal{O}_2$ . Suppose now that  $n=\infty$ . Let us define  $\theta:K_0(\mathcal{O}_\infty)\to K_0(A)$  by  $\theta(k[1_{\mathcal{O}_\infty}])=k[1_A],\ k\in\mathbb{Z}$ . Since  $\mathcal{O}_\infty$  satisfies the UCT,  $\theta$  lifts to some element  $\sigma\in KK(\mathcal{O}_\infty,A)$ . By Theorem 1.4 it follows that  $A\cong C(X)\otimes \mathcal{O}_\infty$ . Finally let us consider the case  $n\in\{3,4,\ldots\}$ . Then  $K_0(\mathcal{O}_n)=\mathbb{Z}/(n-1)$ . Since  $\mathcal{O}_n$  satisfies the UCT, the existence of an element  $\sigma\in KK(\mathcal{O}_n,A)$  such that  $K_0(\sigma)[1_{\mathcal{O}_n}]=[1_A]$  is equivalent to the existence of a morphism of groups  $\theta:\mathbb{Z}/(n-1)\to K_0(A)$  such that  $\theta(\bar{1})=[1_A]$ . This is equivalent to requiring that  $(n-1)[1_A]=0$ .  $\square$ 

As a corollary of Theorem 1.1 we have that  $[X, \operatorname{Aut}(\mathcal{O}_{\infty})]$  reduces to a point. The homotopy groups of the endomorphisms of the stable Cuntz–Krieger algebras were computed in [7]. Let  $v_1, \ldots, v_n$  be the canonical generators of  $\mathcal{O}_n$ ,  $2 \le n < \infty$ .

**Theorem 7.4.** For any compact metrizable space X there is a bijection  $[X, \operatorname{Aut}(\mathcal{O}_n)] \to K_1(C(X) \otimes \mathcal{O}_n)$ . The kth-homotopy group  $\pi_k(\operatorname{Aut}(\mathcal{O}_n))$  is isomorphic to  $\mathbb{Z}/(n-1)$  if k is odd and it vanishes if k is even. In particular  $\pi_1(\operatorname{Aut}(\mathcal{O}_n))$  is generated by the class of the canonical action of  $\mathbb{T}$  on  $\mathcal{O}_n$ ,  $\lambda_{\mathbb{Z}}(v_i) = zv_i$ .

**Proof.** Since  $\mathcal{O}_n$  satisfies the UCT, we deduce that  $\operatorname{End}(\mathcal{O}_n)^* = \operatorname{End}(\mathcal{O}_n)$ . An immediate application of Proposition 6.1 shows that the natural map  $\operatorname{Aut}(\mathcal{O}_n) \hookrightarrow \operatorname{End}(\mathcal{O}_n)$  induces an isomorphism of groups  $[X,\operatorname{Aut}(\mathcal{O}_n)] \cong [X,\operatorname{End}(\mathcal{O}_n)]$ . Let  $\iota:\mathcal{O}_n \to C(X) \otimes \mathcal{O}_n$  be defined by  $\iota(v_i) = 1_{C(X)} \otimes v_i, \ i = 1, \ldots, n$ . The map  $\psi \mapsto \iota(\psi) = \psi(v_1)\iota(v_1)^* + \cdots + \psi(v_n)\iota(v_n)^*$  is known to be a homeomorphism from  $\operatorname{Hom}(\mathcal{O}_n, C(X) \otimes \mathcal{O}_n)$  to the unitary group of  $C(X) \otimes \mathcal{O}_n$ . Its inverse maps a unitary w to the \*-homomorphism  $\psi$  uniquely defined by  $\psi(v_i) = w\iota(v_i), \ i = 1, \ldots, n$ . Therefore

$$[X, \operatorname{Aut}(\mathcal{O}_n)] \cong [X, \operatorname{End}(\mathcal{O}_n)] \cong \pi_0(U(C(X) \otimes \mathcal{O}_n)) \cong K_1(C(X) \otimes \mathcal{O}_n).$$

The last isomorphism holds since  $\pi_0(U(B)) \cong K_1(B)$  if  $B \cong B \otimes \mathcal{O}_{\infty}$ , by [28, Lemma 2.1.7]. One verifies easily that if  $\varphi \in \operatorname{Hom}(\mathcal{O}_n, C(X) \otimes \mathcal{O}_n)$ , then  $u(\widetilde{\psi}\varphi) = \widetilde{\psi}(u(\varphi))u(\psi)$ . Therefore the bijection  $\chi : [X, \operatorname{End}(D)] \to K_1(C(X) \otimes \mathcal{O}_n)$  is an isomorphism of groups whenever  $K_1(\widetilde{\psi}) = \operatorname{id} for all \ \psi \in \operatorname{Hom}(\mathcal{O}_n, C(X) \otimes \mathcal{O}_n)$ . Using the C(X)-linearity of  $\widetilde{\psi}$  one observes that this holds if the n-1 torsion of  $K_0(C(X))$  reduces to  $\{0\}$ , since in that case the map  $K_1(C(X)) \to K_1(C(X) \otimes \mathcal{O}_n)$  is surjective by the Künneth formula.  $\square$ 

**Corollary 7.5.** Let X be a finite dimensional compact metrizable space. The isomorphism classes of unital separable C(SX)-algebras with all fibers isomorphic to  $\mathcal{O}_n$  are parameterized by  $K_1(C(X) \otimes \mathcal{O}_n)$ .

**Proof.** This follows from Theorems 1.1 and 7.4, since the locally trivial principal H-bundles over  $SX = X \times [0, 1]/X \times \{0, 1\}$  are parameterized by the homotopy classes [X, H] if H is a path connected group [17, Cor. 8.4]. Here we take  $H = \operatorname{Aut}(\mathcal{O}_n)$ .  $\square$ 

Examples of nontrivial unital C(X)-algebras with fiber  $\mathcal{O}_n$  over a 2m-sphere arising from vector bundles were exhibited in [36], see also [35].

We need some preparation for the proof of Theorem 1.5. Let G be a group, let  $g \in G$  and set  $\operatorname{End}(G,g) = \{\alpha \in \operatorname{End}(G): \alpha(g) = g\}$ . The pair (G,g) is called *weakly rigid* if  $\operatorname{End}(G,g) \subset$ Aut(G) and *rigid* if  $End(G, g) = \{id_G\}$ .

**Theorem 7.6.** If G is a finitely generated abelian group, then (G, g) is weakly rigid if and only if (G, g) is isomorphic to one of the pointed groups from the list G of Theorem 1.5.

**Proof.** First we make a number of remarks.

- (1) (G, g) is weakly rigid if and only if  $(G, \alpha(g))$  is weakly rigid for some (or any)  $\alpha \in$ Aut(*G*). Indeed if  $\beta \in \text{End}(G, g)$  then  $\alpha \beta \alpha^{-1} \in \text{End}(G, \alpha(g))$ .
- (2) By considering the zero endomorphism of G we see that if (G, g) is weakly rigid and  $G \neq 0$  then  $g \neq 0$ .
  - (3) If  $(G \oplus H, g \oplus h)$  is weakly rigid, then so are (G, g) and (H, h).
- (4) Let us observe that  $(\mathbb{Z}^2, g)$  is not weakly rigid for any g. Indeed, if  $g = (a, b) \neq 0$ , then the matrix  $\binom{1+b^2-ab}{-ab}$  defines an endomorphism  $\alpha$  of  $\mathbb{Z}^2$  such that  $\alpha(g) = g$ , but  $\alpha$  is not invertible since  $det(\alpha) = 1 + a^2 + b^2 > 1$ .
- (5) Let p be a prime and let  $1 \le e_1 \le e_2$ ,  $0 \le s_1 < e_1$ ,  $0 \le s_2 < e_2$  be integers. If (G, g) = $(\mathbb{Z}/p^{e_1}\oplus\mathbb{Z}/p^{e_2},\,p^{s_1}\oplus p^{s_2})$  is weakly rigid then  $0< s_2-s_1< e_2-e_1$ . Indeed if  $s_1\geqslant s_2$  then the matrix  $\begin{pmatrix} 0 & p^{s_1-s_2} \\ 0 & 1 \end{pmatrix}$  induces a noninjective endomorphism of (G, g). Also if  $s_1 < s_2$  and  $s_2 - s_1 \geqslant$  $e_2 - e_1$  then  $p^{e_1}\bar{b} = 0$  in  $\mathbb{Z}/p^{e_2}$ , where  $b = p^{s_2 - s_1}$  and so the matrix  $\begin{pmatrix} 1 & 0 \\ b & 0 \end{pmatrix}$  induces a well-defined noninjective endomorphism of (G, g).
- (6) Let p be a prime and let  $1 \le k$ ,  $0 \le s < e$  be integers. Suppose that  $(\mathbb{Z} \oplus \mathbb{Z}/p^e, k \oplus p^s)$  is weakly rigid. Then k is divisible by  $p^{s+1}$ . Indeed, seeking a contradiction suppose that k can be written as  $k = p^t c$  where  $0 \le t \le s$  and c are integers such that c is not divisible by p. Let d be an integer such that dc-1 is divisible by  $p^e$ . Then the matrix  $\begin{pmatrix} 1 & 0 \\ dp^{s-t} & 0 \end{pmatrix}$  induces a noninjective endomorphism of  $(\mathbb{Z} \oplus \mathbb{Z}/p^e, k \oplus p^s)$ .

Suppose now that (G, g) is weakly rigid. We shall show that (G, g) is isomorphic to one of the pointed groups from the list  $\mathcal{G}$ . Since G is abelian and finitely generated it decomposes as a direct sum of its primary components

$$G \cong \mathbb{Z}^r \oplus G(p_1) \oplus \cdots \oplus G(p_m) \tag{20}$$

where  $p_i$  are distinct prime numbers. Each primary component  $G(p_i)$  is of the form

$$G(p_i) = \mathbb{Z}/p_i^{e_{i1}} \oplus \cdots \oplus \mathbb{Z}/p_i^{e_{in(i)}}$$
(21)

where  $1 \le e_{i1} \le \cdots \le e_{in(i)}$  are positive integers. Corresponding to the decomposition (20) we write the base point  $g = g_0 \oplus g_1 \oplus \cdots \oplus g_m$  with  $g_0 \in \mathbb{Z}^r$  and  $g_i \in G(p_i)$  for  $i \ge 1$ . If  $g_{ij}$  is the component of  $g_i$  in  $\mathbb{Z}/p^{e_{ij}}$ , then it follows from (1), (2) and (3) that we may assume that  $g_{ij} = p^{s_{ij}}$  for some integer  $0 \le s_{ij} < e_{ij}$ . Using (3) and (4) we deduce that r = 1 in (20) and that  $g_0 = k \neq 0$  by (2). We may assume that  $k \geqslant 1$  by (1). Then using (3) and (5) we deduce that for each  $1 \le i \le m$ ,  $0 < s_{ij+1} - s_{ij} < e_{ij+1} - e_{ij}$  for  $1 \le j < n(i)$ . Finally, from (3) and (6) we see that k is divisible by the product  $p_1^{s_{1n(1)}} \cdots p_m^{s_{mn(m)}}$ . Therefore (G,g) is isomorphic to one of the pointed groups on the list  $\mathcal{G}$ .

Conversely, we shall prove that if (G, g) belongs to the list  $\mathcal{G}$  then (G, g) is weakly rigid. This is obvious if G is torsion free i.e. for ( $\{0\}$ , 0) and ( $\mathbb{Z}$ , k) with  $k \ge 1$ .

Let us consider the case when G is a torsion group. Since

$$\operatorname{End}(G(p_1) \oplus \cdots \oplus G(p_m), g_1 \oplus \cdots \oplus g_m) \cong \bigoplus_{i=1}^m \operatorname{End}(G(p_i), g_i)$$

it suffices to assume that G is a p-group,

$$(G,g) = (\mathbb{Z}/p^{e_1} \oplus \cdots \oplus \mathbb{Z}/p^{e_n}, p^{s_1} \oplus \cdots \oplus p^{s_n})$$

with  $0 \le s_i < e_i$  for i = 1, ..., n and  $0 < s_{i+1} - s_i < e_{i+1} - e_i$  for  $1 \le i < n$ . For each  $0 \le i, j \le n$  set  $e_{ij} = \max\{e_i - e_j, 0\}$ . It follows immediately that  $s_i < e_{ij} + s_j$  for all  $i \ne j$ . Let  $\alpha \in \operatorname{End}(G, g)$ . It is well known that  $\alpha$  is induced by a square matrix  $A = [a_{ij}] \in M_n(\mathbb{Z})$  with the property that each entry  $a_{ij}$  is divisible by  $p^{e_{ij}}$  and so  $a_{ij} = p^{e_{ij}}b_{ij}$  for some  $b_{ij} \in \mathbb{Z}$ , see [16]. Since  $\alpha(g) = g$ , we have  $\sum_{j=1}^n \bar{b}_{ij} p^{e_{ij} + s_j} = p^{s_i}$  in  $\mathbb{Z}/p^{e_i}$  for all  $0 \le i \le n$ . Since  $e_{ij} + s_j > s_i$  for  $i \ne j$  and  $e_i > s_i$  we see that  $b_{ii} - 1$  must be divisible by p for all  $1 \le i \le n$ . Since  $\det(A)$  is congruent to  $b_{11} \cdots b_{nn}$  modulo p it follows that  $\det(A)$  is not divisible by p and so  $\alpha \in \operatorname{Aut}(G)$  by [16].

Finally consider the case when  $(G,g) = (\mathbb{Z} \oplus G(p_1) \oplus \cdots \oplus G(p_m), k \oplus g_1 \oplus \cdots \oplus g_m)$ . If  $\gamma \in \operatorname{End}(G,g)$  then there exist  $\alpha_i \in \operatorname{End}(G(p_i),g_i)$  and  $d_i \in G(p_i), 1 \leq i \leq n$ , such that  $\gamma(x_0 \oplus x_1 \oplus \cdots \oplus x_m) = x_0 \oplus (\alpha_1(x_1) + x_0d_1) \oplus \cdots \oplus (\alpha_m(x_m) + x_0d_m)$ . Note that if each  $\alpha_i$  is an automorphism then so is  $\gamma$ . Indeed, its inverse is  $\gamma^{-1}(x_0 \oplus x_1 \oplus \cdots \oplus x_m) = x_0 \oplus (\alpha_1^{-1}(x_1) + x_0c_1) \oplus \cdots \oplus (\alpha_m(x_m)^{-1} + x_0c_m)$ , where  $c_i = -\alpha_i^{-1}(d_i)$ . Therefore it suffices to consider the case m = 1, i.e.

$$(G,g) = (\mathbb{Z} \oplus \mathbb{Z}/p^{e_1} \oplus \cdots \oplus \mathbb{Z}/p^{e_n}, k \oplus p^{s_1} \oplus \cdots \oplus p^{s_n}),$$

and (G, g) is on the list  $\mathcal{G}$  (e). In particular  $k = p^{s_n+1}\ell$  for some  $\ell \in \mathbb{Z}$ . Let  $\gamma \in \operatorname{End}(G, g)$ . Then there exists  $\alpha \in \operatorname{End}(G(p))$  and  $d \in G(p)$  such that  $\gamma(x_0 \oplus x) = x_0 \oplus (\alpha(x) + x_0 d)$ . Just as above,  $\alpha$  is induced by a square matrix  $A \in M_n(\mathbb{Z})$  of the form  $A = [b_{ij} p^{e_{ij}}] \in M_n(\mathbb{Z})$  with  $b_{ij} \in \mathbb{Z}$ ,  $e_{ij} = \max\{e_i - e_j, 0\}$ . Since  $\gamma(g) = g$  we have that  $p^{s_n+1}\ell d_i + \sum_{j=1}^n \bar{b}_{ij} p^{e_{ij}+s_j} = p^{s_i}$  in  $\mathbb{Z}/p^{e_i}$  for all  $0 \le i \le n$ , where the  $d_i$  are the components of d. By reasoning as in the case when G was a torsion group considered above, since  $s_n + 1 > s_i$  for all  $1 \le i \le n$ ,  $e_{ij} + s_j > s_i$  for all  $i \ne j$  and  $e_i > s_i$ , it follows again that each  $b_{ii} - 1$  is divisible by p and that the endomorphism  $\alpha$  of G(p) induced by the matrix A is an automorphism. We conclude that  $\gamma$  is an automorphism.  $\square$ 

#### 7.5. Proof of Theorem 1.5

**Proof.** (ii) and (iii) Let D be a unital Kirchberg algebra such that D satisfies the UCT and  $K_*(D)$  is finitely generated. Then D is KK-semiprojective by Proposition 3.14 and  $KK(D, D)^{-1} = \{\alpha \in KK(D, D): K_*(\alpha) \text{ is bijective}\}$ . In conjunction with Theorem 3.1, this shows that all unital \*-endomorphisms of D are KK-equivalences if and only if both  $(K_0(D), [1_D])$  and  $(K_1(D), [0])$  are weakly rigid. Equivalently,  $K_1(D) = 0$  and  $(K_0(D), [1_D])$  is weakly rigid. By Theorem 7.6  $(K_0(D), [1_D])$  is weakly rigid if and only if it isomorphic to one pointed groups from the list  $\mathcal{G}$  of Theorem 1.5. We conclude the proof of (ii) and (iii) by applying Theorem 1.4.

(i) By Theorem 1.1 both  $\mathcal{O}_2$  and  $\mathcal{O}_{\infty}$  have the automatic triviality property. Conversely, suppose that D has the automatic triviality property, where D is a unital Kirchberg algebra satisfying

the UCT and such that  $K_*(D)$  is finitely generated. We shall prove that D is isomorphic to either  $\mathcal{O}_2$  or  $\mathcal{O}_{\infty}$ .

Let Y be a finite connected CW-complex and let  $\iota: D \to C(Y) \otimes D$  be the map  $\iota(d) = 1 \otimes d$ . Let  $[D, C(Y) \otimes D]$  denote the homotopy classes of unital \*-homomorphisms from D to  $C(Y) \otimes D$ . By Theorem 3.1 the image of the map  $\Delta: [D, C(Y) \otimes D] \to KK(D, C(Y) \otimes D)$  defined by  $[\varphi] \mapsto KK(\varphi) - KK(\iota)$  coincides with the kernel of the restriction morphism  $\rho: KK(D, C(Y) \otimes D) \to KK(\mathbb{C}1_D, C(Y) \otimes D)$ .

We claim that  $\ker \rho$  must vanish for all Y. Let  $h \in \ker \rho$ . Then there is a unital \*-homomorphism  $\varphi: D \to C(Y) \otimes D$  such that  $\Delta[\varphi] = h$ . By Theorem 1.4, each unital endomorphism of D induces a KK-equivalence. Therefore, by Proposition 6.1 there is a \*-homomorphism  $\Phi: D \to C(Y) \otimes D$  such that  $\Phi_y \in \operatorname{Aut}(D)$  for all  $y \in Y$  and  $KK(\Phi) = KK(\varphi)$ . Therefore  $\Delta[\Phi] = KK(\Phi) - KK(\iota) = h$ . By hypothesis, the  $\operatorname{Aut}(D)$ -principal bundle constructed over the suspension of Y with characteristic map  $y \mapsto \Phi_y$  is trivial. It follows then from [17, Thm. 8.2, p. 85] that this map is homotopic to the constant map  $Y \to \operatorname{Aut}(D)$  which shrinks Y to  $\operatorname{id}_D$ . This implies that  $\Phi$  is homotopic to  $\iota$  and hence h = 0.

Let us now observe that  $\ker \rho$  contains subgroups isomorphic to  $\operatorname{Hom}(K_1(D), K_1(D))$  and  $\operatorname{Ext}(K_0(D), K_0(D))$  if  $Y = \mathbb{T}$ , since D satisfies the UCT. It follows that both these groups must vanish and so  $K_1(D) = 0$  and  $K_0(D)$  is torsion free. On the other hand,  $(K_0(D), [1_D])$  is weakly rigid by the first part of the proof. Since  $K_0(D)$  is torsion free we deduce from Theorem 7.6 that either  $K_0(D) = 0$  in which case  $D \cong \mathcal{O}_2$  or that  $(K_0(D), [1_D]) \cong (\mathbb{Z}, k), k \geqslant 1$ , in which case  $D \cong M_k(\mathcal{O}_\infty)$  by the classification theorem of Kirchberg and Phillips.

To conclude the proof, it suffices to show that  $\ker \rho \neq 0$  if  $D = M_k(\mathcal{O}_{\infty})$ ,  $k \geqslant 2$  and Y is the two dimensional space obtained by attaching a disk to a circle by a degree-k map. Since  $K_0(C(Y) \otimes \mathcal{O}_{\infty}) \cong \mathbb{Z} \oplus \mathbb{Z}/k$  we can identify the map  $\rho$  with the map  $\mathbb{Z} \oplus \mathbb{Z}/k \to \mathbb{Z} \oplus \mathbb{Z}/k$ ,  $x \mapsto kx$  and so  $\ker \rho \cong \mathbb{Z}/k \neq 0$  if  $k \geqslant 2$ .  $\square$ 

#### 7.6. Added in proof

Some of the results from this paper are further developed in [9]. Theorem 1.2 was shown to hold for all stable Kirchberg algebras D. The assumption that X is finite dimensional is essential in Theorem 1.1. Theorem 1.5(ii) extends as follows:  $\mathcal{O}_2$ ,  $\mathcal{O}_\infty$  and  $B \otimes \mathcal{O}_\infty$ , where B is a unital UHF algebra of infinite type, are the only unital Kirchberg algebras which satisfy the UCT and have the automatic triviality property in the unital sense.
