incurred the rates of major adverse cardiovascular events and definite stent thrombosis at 30 days.

Results: The median time from randomization to angiography was 48 minutes, and the median time difference between the two treatment strategies was 31 minutes. The two co-primary end points did not differ significantly between the pre-hospital and in-hospital groups (86.8% vs 87.6% and 82.6% vs 83.1% respectively, p=NS). The rates of major adverse cardiovascular events did not differ significantly between the two study groups. The rates of definite stent thrombosis were lower in the pre-hospital group than in the in-hospital group (0% vs. 0.8% in the first 24 hours, p=0.008; 0.2% vs. 1.2% at 30 days, p=0.02). Rates of major bleeding events were low and virtually identical in the two groups.

Conclusion: Pre-hospital administration of Ticagrelor in patients with acute STEMI appeared to be safe but did not improve pre-PCI coronary reperfusion. It may, however, reduce the risk of post-PCI stent thrombosis. Results are also aligned with the new ESC 2014 Guidelines which recommended P2Y12 inhibitors to be given at first medical contact for patient undergoing primary PCI. These will particularly suitable in India where patients are arriving late at the cath lab centers. For STEMI patients undergoing PCI, it is advisable to give Ticagrelor in pre-hospital (in Ambulance or at secondary care) setting in Indian scenario.

Study on correlation of obesity with short-term prognosis in acute myocardial infarction

K.F. Rajesh, V. Haridasan, M.N. Krishnan
Govt. Medical College, Kozhikode, India

Background: Obese patients with established coronary artery disease (CAD) have reduced mortality compared to normal or low body mass index (BMI) patients, irrespective of whether treated with medically, percutaneous coronary intervention (PCI) or coronary artery bypass surgery (CABG). The reason for the paradoxical U or J-shaped relation between BMI and adverse outcome is not yet clearly understood. We sought to evaluate the association of BMI and waist circumference at the time of presentation in patients with myocardial infarction with one-year adverse cardiac events.

Methods: In this prospective cohort study we included consecutive patients with acute myocardial infarction (MI) admitted to a tertiary care hospital during a period of one year. Upon admission, BMI and waist circumference were measured. Patients were followed-up for a period of one year for primary composite outcome of death or nonfatal MI and correlated with BMI and waist circumference categories. Body mass index was classified as underweight (BMI <18.5 kg/m²), normal weight (18.5-22.9 kg/m²), overweight (23-24.9 kg/m²), obese class I (25 to 29.9 kg/m²) or obese class II (>30 kg/m²). Waist circumference greater than 90 cm in men and 80 cm in women was categorized high.

Results: There were 703 patients (males 559 (79.5%), females 144 (20.4%). Among them 100(14.2%) were underweight, 351(49.9%) were of normal weight and 122 (17.3%) were overweight. Class I obesity was seen in 112 (15.9%) and class II obesity in 18(2.5%) patients. There were 227(32%) patients with high waist circumference. Over a period of one year, there were 40 (5.6%) deaths including 18 in-hospital deaths. Combined nonfatal MI and death at one year was 128(18.2%). Incidence of primary outcome was 25.0% in low BMI group, 19.9% in normal BMI group, 13.1% in overweight group, 13.4 % in obese class I and 11.1 % in obese class II group. In univariate analysis, the inverse correlation of obesity and primary outcome was significant by linear-by-linear association (p value = 0.007). In-hospital mortality showed no significant correlation with obesity parameters. In one year follow up period, 12.8% in high waist circumference group and 20.8 % in normal waist circumference group had primary outcome (P value=0.01). In-hospital mortality was 2.5% in high waist circumference group and 3.4% in normal waist circumference group (P value = 0.052).

Both BMI and waist circumference lost their predictive value in multivariate analysis.

Conclusions: Low BMI and normal waist circumference were associated with a worse short term outcome in patients with acute MI. After adjusting for other variables, neither BMI nor waist circumference independently predicted cardiac events or death after acute MI.

Cardiac rehabilitation in a major metropolitan in South India: Factors influencing patient participation

Priya Chockalingam, N. Sakthi Vinayagam, N. Ezhil Vani, V. Chockalingam
Cardiac Wellness Institute, Chennai, India

Background: The higher risk for coronary heart disease (CHD) in South Asians at a younger age is attributed to the higher levels of conventional risk factors. However, cardiac rehabilitation (CR) is yet to gain momentum in the subcontinent. We aimed to analyse the factors that influence participation in a CR program in a single center in South India.

Methods: All patients referred for CR between May and July 2014 were included. Age, gender, work status, residence address, past medical history and treatment history were documented. A typical CR program (TCR) included 24 sessions spread over 12 weeks, each session lasting 90 minutes. A modified CR program (MCR) had fewer sessions and a home-based CR program (HCR) was followed at home with a monthly visit to the CR facility. Patients were motivated by the physician to attend group sessions at a fixed schedule based on their convenience. CR was exercise-based with education on balanced diet and stress management, and psychosocial counseling.

Results: The study cohort included 24 patients with coronary heart disease (58±9 years,88% males). Working individuals (n=17), retired people (n=5) and homemakers (n=2) constituted the cohort. While majority lived in the same city as the CR facility, 8 (33%) resided outside the city with commute time >3 hours. CR program was attended by 14 (58%) subjects of which 8 (57%) were TCR, 5 (36%) MCR and 1(7%) HCR. Of the 10 patients not following a CR program, long distance (n=8), dependent family member (n=1) and debilitating spinal tuberculosis (n=1) were the reasons.

Conclusions: Secondary prevention of CHD is the definitive solution to the growing rate of complications and spiraling healthcare costs in India. This study has demonstrated that patients can be motivated to attend a comprehensive CR program, with some modification to suit their requirements. Lack of easily accessible CR facilities is a deterring factor for participation.

Relationship between ankle brachial index and coronary angiographic findings
