

The Role of Hydrogen Sulfide in Renal System

Xu Cao and Jin-Song Bian*

Department of Pharmacology, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore

Hydrogen sulfide has gained recognition as the third gaseous signaling molecule after nitric oxide and carbon monoxide. This review surveys the emerging role of H₂S in mammalian renal system, with emphasis on both renal physiology and diseases. H₂S is produced redundantly by four pathways in kidney, indicating the abundance of this gaseous molecule in the organ. In physiological conditions, H₂S was found to regulate the excretory function of the kidney possibly by the inhibitory effect on sodium transporters on renal tubular cells. Likewise, it also influences the release of renin from juxtaglomerular cells and thereby modulates blood pressure. A possible role of H₂S as an oxygen sensor has also been discussed, especially at renal medulla. Alternation of H₂S level has been implicated in various pathological conditions such as renal ischemia/reperfusion, obstructive nephropathy, diabetic nephropathy, and hypertensive nephropathy. Moreover, H₂S donors exhibit broad beneficial effects in renal diseases although a few conflicts need to be resolved. Further research reveals that multiple mechanisms are underlying the protective effects of H₂S, including anti-inflammation, anti-oxidation, and anti-apoptosis. In the review, several research directions are also proposed including the role of mitochondrial H₂S in renal diseases, H₂S delivery to kidney by targeting D-amino acid oxidase/3-mercaptopyruvate sulfurtransferase (DAO/3-MST) pathway, effect of drug-like H₂S donors in kidney diseases and understanding the molecular mechanism of H₂S. The completion of the studies in these directions will not only improves our understanding of renal H₂S functions but may also be critical to translate H₂S to be a new therapy for renal diseases.

Keywords: hydrogen sulfide, H₂S, renal physiology, acute kidney injury, chronic kidney disease, diabetic nephropathy

INTRODUCTION

Hydrogen sulfide has been regarded as a toxic gas for 100s of years (Smith and Gosselin, 1979). It can directly inhibit the activity of several essential enzymes in human namely cytochrome c oxidase (Reiffenstein et al., 1992), carbonic anhydrase (Nicholson et al., 1998), monoamine oxidase (Warenycia et al., 1989), and Na⁺/K⁺ ATPase (Reiffenstein et al., 1992), thereby causing toxicity.

Abbreviations: AC, adenylate cyclase; AMPK, 5' AMP-activated protein kinase; AOAA, aminooxyacetic acid; CaMTg, pancreatic β-cell specific calmodulin-overexpressing transgenic; CAT, cysteine aminotransferase; CBS, cystathionine β-synthase; CKD, chronic kidney disease; CO, carbon monoxide; CSE, cystathionine γ-lyase; DAO, D-amino acid oxidase; DN, diabetic nephropathy; EDHF, endothelium-derived hyperpolarizing factor; EDRE, endothelium-derived relaxing factor; GFR, glomerular filtration rate; H₂S, hydrogen sulfide; IRI, ischemia/reperfusion injury; JG, juxtaglomerular; MAPK, mitogen-activated protein kinase; MMP-9, matrix metalloproteinase-9; NF-κB, nuclear factor-κB; NKA, Na⁺/K⁺ ATPase; NKCC, Na⁺/K⁺/2Cl⁻ cotransporter; NO, nitric oxide; PAG, DL-propargylglycine; RAS, renin-angiotensin system; ROS, reactive oxygen species; STZ, streptozotocin; U_K-V, urinary potassium; UNa-V, urinary sodium; VEGF, vascular endothelial growth factor; 3-MP, 3-mercaptopyruvate; 3-MST, 3-mercaptopyruvate sulfurtransferase.

However, the image of H₂S has been largely expanded since the revelation of H₂S as an endogenous neuronal modulator by Kimura's group in Abe and Kimura (1996). Thereafter, the physiological significance of H₂S has been extensively studied especially in central nervous system (Zhang and Bian, 2014) and cardiovascular system (Liu et al., 2012). Emerging evidence has suggested that H₂S also actively regulates renal function and is implicated in numerous kidney diseases in recent years. Here in this review, recent studies regarded the role of H₂S in both kidney physiology and diseases will be discussed.

PHYSICAL AND CHEMICAL PROPERTIES OF H₂S

Hydrogen sulfide exists as a colorless gas with a strong rotten egg smell at room temperature and ambient pressure. The human nose can detect a concentration of 400-fold lower than its toxic level (Wang, 2002), whereas, long term exposure can cause desensitization of olfactory nerves to H₂S (Li et al., 2009). Distinct from the other gaseous transmitters like NO and CO, H₂S is a weak acid and hence able to readily dissolve in water. Based on its PKa, it is estimated that there will be 14% H₂S gas, 86% HS⁻ and a trace of S²⁻ in physiological condition (pH 7.4, 37°C; Li et al., 2009). Moreover, H₂S gas is highly lipophilic which allows it freely to penetrate into the cell membrane of all types and become biologically active (Mathai et al., 2009).

H₂S GENERATION IN THE KIDNEY

Three traditional H₂S synthesizing pathways have been identified in mammals including CSE (EC 4.4.1.1), CBS (EC 4.2.1.22), and 3-MST (EC 2.8.1.2) coupled with CAT (EC 2.6.1.3) pathways. The mechanisms underlying these traditional pathways can be found in our previous review in detail (Liu et al., 2012). In short, CSE firstly dimerizes two L-cysteine to L-cystine followed by transforming it into pyruvate, NH₃ and thiocysteine. The resulted thiocystein is then used as a substrate by CSE to react with other thiols to generate H₂S (Stipanuk and King, 1982). CBS catalyzes the reaction between L-cysteine and homocystein into cystathionine and H₂S (Szabo, 2007). However, 3-MST is unable to directly use L-cysteine as a substrate as its counterpart does. L-cysteine has to be transformed into 3-MP by CAT which is then catalyzed by 3-MST into pyruvate and H₂S (Shibuya et al., 2009). It is worth mentioning that both CSE and CBS require pyridoxal 5'-phosphate as a cofactor to synthesize H₂S, while 3-MST is dependent on zinc (Li et al., 2009). In addition, CSE and CBS mainly locate in cytosol yet they can translocate into mitochondria in some oxidative conditions (Fu et al., 2012), whereas 3-MST resides and generates H₂S in mitochondria (Kimura, 2011).

A fourth H₂S generation pathway namely DAO/3-MST pathway was discovered recently by Kimura's group (Shibuya et al., 2013). In the study, they showed that kidney lysate can produce 60 times more H₂S when using D-cysteine as substrate comparing with L-cysteine. Further, the underlying mechanism

was studied. Specifically, D-cysteine is transformed into 3-MP by peroxisome located DAO. Due to metabolite exchanges between peroxisome and mitochondria, 3-MP is imported into mitochondria and catalyzed into H₂S by 3-MST. Since DAO is only located in brain and kidney, this H₂S generating pathway is believed to exclusively exist in brain and kidney.

Hydrogen sulfide generation is abundant in kidney given the presence of all the above mentioned pathways in this organ (Figure 1). Currently, it is believed that CSE and CBS are the dominated enzymes for H₂S generation in kidney. The presence of these two enzymes was firstly demonstrated in 1980s by using their inhibitors (Stipanuk and Beck, 1982). Later on, House et al. (1997) suggested that both enzymes were mainly located on renal proximal tubules within the renal cortex by comparison with marker enzymes of known location. This finding was supported by several other studies using different methods (Ishii et al., 2004; Li et al., 2006; Tripatara et al., 2009). However, inconsistent results have been reported regarding the existence of these two enzymes in glomerulus which needs to be resolved (Aminzadeh and Vaziri, 2012; Bos et al., 2013; Yamamoto et al., 2013). In addition, definitive evidence has suggested the presence of 3-MST in kidney (Aminzadeh and Vaziri, 2012; Shibuya et al., 2013; Kimura, 2014; Pan et al., 2015), however, the significance of 3-MST mediated H₂S generating pathway has not been well-acknowledged in both kidney physiology and diseases due to limited reports. Nevertheless, the revelation of the unique DAO/3-MST pathway in kidney and brain may imply a significant role of 3-MST mediated H₂S generation in these organs. This will be an interesting area open to explore in the next years.

EFFECT OF H₂S ON RENAL PHYSIOLOGY

H₂S Effect on Renal Excretory Function

The necessity of H₂S producing enzymes have long been recognized in the kidney due to their critical effect on homocysteine metabolism (Stipanuk, 2004), however, the effect of H₂S itself on renal function was not studied until recently. Intra-renal infusion of H₂S donor NaHS is able to increase GFR, UNa-V and potassium (Uk-V) excretion (Xia et al., 2009; Ge et al., 2014). Moreover, the effect is closely mimicked by the infusion of L-cysteine, an H₂S generating substrate (Xia et al., 2009). In addition, inhibition of endogenous H₂S production by AOAA (CBS inhibitor) plus PAG (CSE inhibitor) leads to the decrease of GFR, UNa-V and Uk-V, suggesting that H₂S regulates renal function in physiological conditions. However, either AOAA or PAG alone fails to produce any effect on renal function implicating a compensatory effect between CBS and CSE on renal regulation which has been confirmed by another study (Roy et al., 2012). Hypothesis concerning the effects of H₂S on sodium transporters was formed and tested thereafter. The results showed that H₂S significantly inhibited the activity of NKCC and NKA which may account for its effect on renal function (Figure 2A). Recently, the mechanism of the inhibitory effect of H₂S on NKA was studied by Zhu's group (Ge et al., 2014). In

FIGURE 1 | Endogenous synthesis of H₂S by four pathways in renal system. (1) CBS mediated H₂S synthesis by using L-cysteine as the substrate in cytosol; (2) CSE mediated H₂S synthesis with L-cysteine as the substrate in cytosol; (3) CAT transforms L-cysteine into 3MP which is further catalyzed by 3-MST into H₂S in mitochondria; (4) Peroxisome resident DAO catalyzes D-cysteine into 3MP which is then exchanged into mitochondria and utilized by 3-MST for the production of H₂S in mitochondria. CBS, cystathionine β-synthase; CSE, cystathionine γ-lyase; 3-MST, 3-mercaptopyruvate sulfurtransferase; CAT, cysteine aminotransferase; DAO, D-amino acid oxidase; 3MP, 3-mercaptopyruvate.

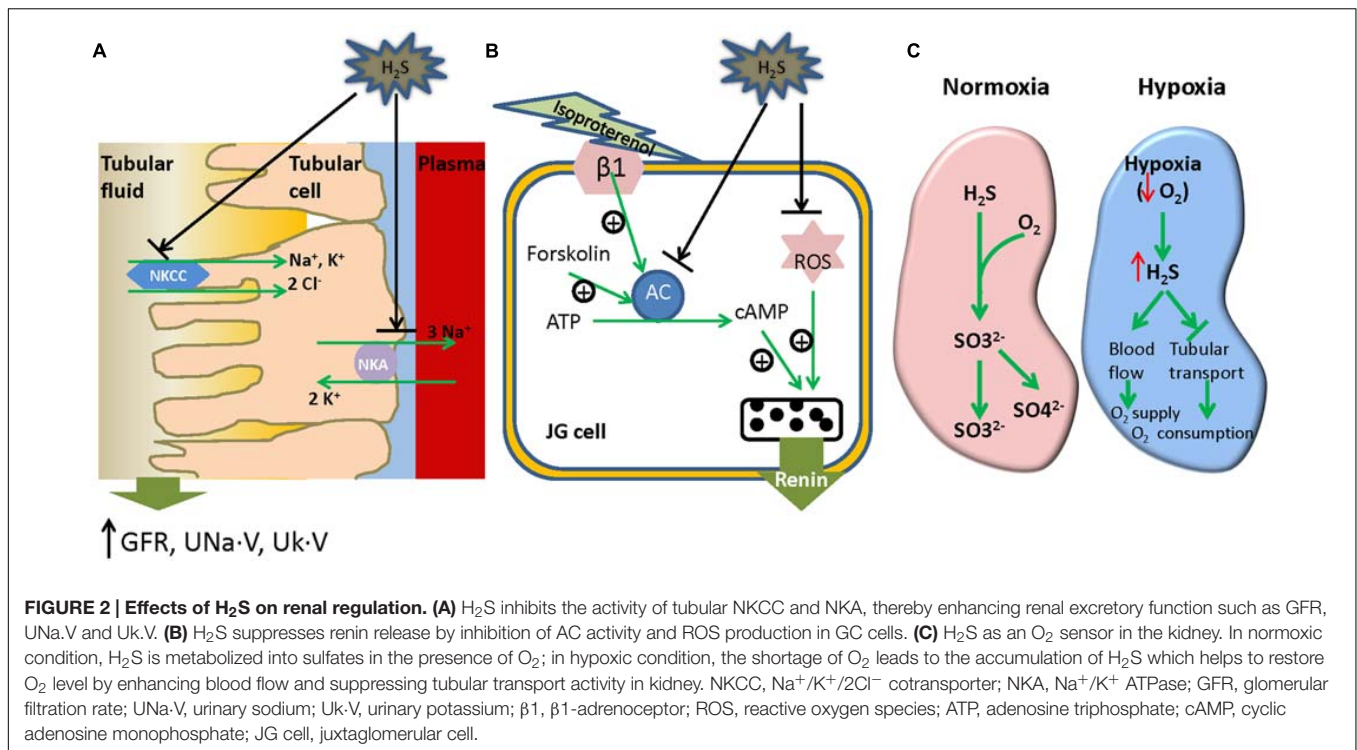

their study, they showed that NaHS promoted NKA endocytosis by directly activating epidermal growth factor receptor (EGFR) in renal tubular epithelia cells. Moreover, EGFR cys797 mutation fully abolished the effect of H₂S suggesting a direct interaction between H₂S and this cysteine residue. Taken together, both endogenous and exogenous H₂S are able to increase GFR, UNa⁺V, and U_k-V excretion probably through the inhibitory effect on sodium transporters like NKCC and NKA.

Hydrogen sulfide increases Cl⁻/HCO₃⁻ exchanger activity in various tissues like aortic tissues (Liu and Bian, 2010) and vascular smooth muscle cells (Lee et al., 2007). However, the effect of H₂S on the exchanger in kidney is still unknown. It is likely that H₂S can also enhance the activity of Cl⁻/HCO₃⁻ exchanger in renal system. Considering the critical role of Cl⁻/HCO₃⁻ exchanger in regulating the excretion of ions and homeostatic maintenance of physiological pH, it will be of great value to

reveal the effect of H₂S on Cl⁻/HCO₃⁻ exchanger activity and the subsequent consequence in kidney.

H₂S Effect on Renin Release

The RAS is a renovascular hormone system involved in the regulation of plasma sodium concentration and blood pressure (BP). Renin release from JG cells determines RAS activity and the process is known to be regulated by intracellular cAMP (Peters et al., 1993; Gambaryan et al., 1998; Schweda et al., 2007). Moreover, H₂S was reported to downregulate cAMP level in several cell types (Lim et al., 2008; Yong et al., 2008), implying that H₂S may modulate renin release. This was demonstrated by our group in Lu et al. (2010). It was found that NaHS inhibited the upregulation of renin mRNA and protein level in a model of renovascular hypertension accompanying with a reduction of intracellular cAMP level.

This is supported by another study (Lu et al., 2012) showing that H₂S regulates renin degranulation in As4.1 and rat renin-rich kidney cells stimulated by isoproterenol, forskolin or 3-isobutyl-1-methylxanthine. Further study demonstrated that H₂S significantly suppressed the stimulated AC activity in these cells. Overexpression of CSE also attenuates isoproterenol-induced renin release suggesting that endogenous H₂S may also involve in the process. However, the mechanism underlying the inhibitory effect of H₂S on AC remains to be determined, such as the identification of AC isoform(s) accounting for H₂S effect and the molecular interaction between H₂S and the AC isoform(s). Besides AC, ROS was recently reported to be a target of H₂S for its effect on renin reduction in DN suggesting participation of multiple mechanisms in the process (Xue et al., 2013). The effect of H₂S on renin activity in normal rats has also been investigated (Lu et al., 2010). The results showed that neither NaHS administration nor inhibition of endogenous H₂S influenced renin activity implying that H₂S may only modulate renal activity when RAS is overactivated. The effect of H₂S on renin activity has been illustrated in **Figure 2B**.

H₂S as an O₂ Sensor in the Kidney

Essentially all H₂S generation is independent of O₂; however, the metabolism of H₂S is a process highly relying on O₂ (Olson, 2015). Accumulating evidence suggests that H₂S is an O₂ sensor in kidney, especially in medulla (**Figure 2C**). The availability of O₂ in renal medulla is lower compared with that in renal cortex resulting in a higher abundance of H₂S in this region (Koning et al., 2015). Provided mitochondria can use H₂S as an electron donor for ATP production (Fu et al., 2012; Teng et al., 2013),

it will be interesting to hypothesize that H₂S might be a direct source of energy in renal medulla. During hypoxia, O₂ reduction leads to further accumulation of H₂S which help to recover O₂ supply by increasing medullary blood flow and inhibition of tubular transport (Beltowski, 2010). In addition, CBS and CSE can translocate into mitochondria and stimulate H₂S production under hypoxic circumstances (Fu et al., 2012; Teng et al., 2013). The mitochondria derived H₂S may directly participate in ATP production. Currently, emerging physiological evidence for H₂S mediated O₂ sensing has also been suggested in various O₂ sensing tissues including cardiovascular system (Olson et al., 2006; Olson and Whitfield, 2010), respiratory system (Hu et al., 2008), gastrointestinal tract (Dombkowski et al., 2011) et al. However, the downstream effectors of H₂S mediated O₂ sensing remains to be determined.

H₂S IN ACUTE KIDNEY INJURY

Acute kidney injury (formerly known as acute renal failure) is defined as a syndrome characterized by rapid loss of the kidney's excretory function. It is the clinical manifestation of several disorders that affect the kidney acutely (Bellomo et al., 2012). Here, H₂S effects in three types of acute kidney injury will be discussed namely renal IRI, obstructive nephropathy, and cisplatin nephrotoxicity.

H₂S in Renal Ischemia/Reperfusion Injury

Renal IRI is a major cause of acute kidney injury. The pathophysiological mechanism underlying renal IRI is very

complex containing ATP depletion, calcium overload, ROS generation, apoptotic and inflammatory responses et al (Eltzschig and Eckle, 2011). The engagement of endogenous H₂S in renal IRI has been thoroughly demonstrated in various studies. Specifically, both mRNA and protein levels of CSE and CBS are apparently reduced upon IRI along with the reduction of H₂S level in kidney and plasma (Xu et al., 2009; Han et al., 2015), although mechanisms underlying IRI caused CSE and CBS reduction are still not revealed. In addition, inhibition of either CSE or CBS by their pharmacological inhibitors severely aggravates renal damage (Tripatara et al., 2008; Han et al., 2015) indicating that the ischemic renal injury might, at least in part, results from the impaired endogenous production of H₂S. The implication is supported by a recent finding that CSE-deficiency associates with increased renal damage and mortality after renal IRI which might be due to the enhanced production of ROS (Bos et al., 2013). Subsequently, the effect of exogenous H₂S was extensively studied in various renal IRI scenarios (Tripatara et al., 2008, 2009; Bos et al., 2009, 2013; Xu et al., 2009; Simon et al., 2011; Hunter et al., 2012; Zhu et al., 2012; Azizi et al., 2015; Han et al., 2015; Ahmad et al., 2016) which have been summarized in **Table 1**. In most studies, an H₂S donor, NaHS, was employed and exerted protective effects likely through anti-inflammatory, anti-apoptotic, and anti-oxidative responses. Comparing with new generation synthetic H₂S donors like GYY4137, NaHS is less physiologically accurate H₂S producer (Li et al., 2008; Yu et al., 2010). Recently, GYY4137 was shown to attenuate heart damage by inhibiting activation of NF- κ B and MAPK signaling in a rat model of myocardial IRI (Meng et al., 2015a,b). Thus, studies are warranted to study whether slow H₂S donors like GYY4137 can protect kidney from IRI. Besides, it is worth noting that AP39, a mitochondrially targeted donor of H₂S, was recently found to inhibit intracellular ROS formation caused by glucose oxidase and protect kidney from IRI caused damage in rats (Ahmad et al., 2016). The study implies the importance of mitochondria H₂S in the pathology of renal IRI which needs to be determined in the future.

H₂S in Obstructive Nephropathy

Obstructive nephropathy is a type of renal injury caused by obstruction of the genitourinary tract. Renal fibrosis after ureteral obstruction is implicated in the development of obstructive nephropathy (Boor et al., 2010). Hu's group showed that ureteral obstruction impaired endogenous production of H₂S by reducing the expression level of CBS (Song et al., 2014). Renal fibrosis is attenuated when exogenous H₂S is administered suggesting an inhibitory effect of H₂S on renal fibrosis (Song et al., 2014). In cultured kidney fibroblast, NaHS is able to inhibit cell proliferation and block the differentiation into myofibroblasts by suppressing transforming growth- β 1-Smad and MAPK signaling pathways (Song et al., 2014). Furthermore, administration of NaHS also prevents the disruption of renal function caused by ureteral obstruction (Jiang et al., 2014; Song et al., 2014; Dursun et al., 2015). A recent study from Sener's group (Lin et al., 2016) showed that H₂S slow releasing donor GYY4137 mitigated cortical loss, inflammatory damage and tubulointerstitial fibrosis in a rat model of obstructive nephropathy. Taken together, these

results suggest a potential use of H₂S donor as a rescue in obstructive nephropathy.

H₂S in Cisplatin Nephrotoxicity

Cisplatin is a major therapeutic drug for solid tumors, but causes severe nephrotoxicity. Over 30% of patients receiving high dose cisplatin develop renal dysfunction (Pabla and Dong, 2008). However, effective treatment of cisplatin induced renal failure is still lacking. Extensive research revealed that oxidative stress and inflammatory response are the major driving forces for cisplatin induced renal toxicity (Pabla and Dong, 2008; Peres and da Cunha, 2013). Given the well-known inhibitory effects of H₂S on oxidative stress and inflammation (Łowicka and Beltowski, 2006), it is reasonable to hypothesize that H₂S is protective against cisplatin nephrotoxicity. However, the role of H₂S is rather controversial due to conflicting data in this field. Coimbra and others (Della Coletta Francescato et al., 2011) firstly showed that cisplatin upregulated the expression level of CSE after 3 days upon cisplatin treatment in a rat model. When PAG was administered with cisplatin, it was found that PAG abolished the upregulation of CSE and rescued cisplatin caused renal damage by suppressing inflammation and apoptosis (Della Coletta Francescato et al., 2011). In contrast to this study, administration of NaHS ameliorates the kidney dysfunction and damage in cisplatin treated rat (Ahangarpour et al., 2014). Liu et al. (2016) recently showed that both CSE and CBS levels were severely decreased upon cisplatin treatment in mouse after 3 days. However, pretreatment with H₂S slow releasing donor GYY4137 aggravates cisplatin induced renal damage by increasing inflammatory response (Liu et al., 2016). However, several defects on the use of GYY4137 need to be pointed out in the study. As they used a rather low dose of GYY4137 (21 mg/kg), it is possible that H₂S might be not generated sufficiently (Li et al., 2008; Yu et al., 2010; Meng et al., 2015a,b; Lin et al., 2016). In addition, to rule out the possibility that the chemical backbone of GYY4137 molecule has aggravated cisplatin nephrotoxicity, ZYJ1122 (Lee et al., 2011), a structure analog of GYY4127, should be included for the study. Despite the promising protective effect of H₂S, however, it is still far from the conclusion that H₂S is protective in cisplatin nephrotoxicity. In future, more studies are still needed to further investigate (1) the change of CSE and CBS expression level in a time course dependant manner; (2) the effect of endogenous H₂S by using genetic mouse rather than non-specific CBS/CSE inhibitors; (3) the effect of exogenous H₂S by using different H₂S (NaHS, GYY4137, AP39) donors in parallel.

H₂S IN CHRONIC KIDNEY DISEASE

Chronic kidney disease is a general term for heterogeneous disorders affecting kidney structure and function. In western countries, it is generally associated with old age, diabetes, hypertension, obesity, and cardiovascular disease (Levey and Coresh, 2012). Diabetic nephropathy and hypertensive nephropathy are considered as presumed pathological entities. The role of H₂S in these two types of CKD will be reviewed below.

TABLE 1 | Comparison of the renal protective effect of H₂S against ischemic/reperfusion injury.

Treatment	I/R protocol	Species/tissue	Effects of H ₂ S	Mechanism	Reference
NaHS (100 μmol/kg, i.p., 30 min prior to ischemia)	I (30 min)/R (24 h)	C57BL/6 mice	Improved renal function	–	Tripatara et al., 2008
NaHS (1 mg/kg, i.p., 15 min prior to ischemia)	I (30 min)/R (24 h)	C57BL/6 mice	Improved renal function; reduced renal injury, and mortality	Anti-oxidation	Bos et al., 2009
NaHS (100 μg/kg, i.p., 15 min prior to ischemia)	I (45 min)/R (6 h)	Sprague-Dawley rat	Improved renal function; reduced renal injury	Anti-oxidation; anti-apoptosis	Tripatara et al., 2009
NaHS (500 μg/kg, i.p., first dose at 2 days after ischemia; then daily)	I (30 min)/R (8 days)	C57BL/6 mice	Accelerated kidney recovery and tubular cell regeneration	Anti-oxidation	Xu et al., 2009
NaHS (100 μmol/kg, topically onto the kidneys 15 min before ischemia and 5 min before reperfusion)	I (45 min)/R (6 h)	Wistar rat	Improved renal function; reduced renal injury	Anti-apoptosis; anti-MAPK; anti-NF-κB	Simon et al., 2011
H ₂ S (100 ppm, 30 prior to ischemia)	I (30 min)/R (24 h)	C57BL/6 mice	Improved renal function; reduced renal injury	Induction of hypometabolism	Hunter et al., 2012
Na ₂ S (initial bolus 0.2 mg/kg followed by continuous i.v. 2 mg/kg/h during the 2 h before aortic occlusion, 0.5 mg/kg/h during the 90 min of aortic occlusion, and 1 mg/kg/h during the 8-h reperfusion period)	I (2 h)/R (8 h)	Local pig	Improved renal function; reduced renal injury	Anti-apoptosis; anti-oxidation; anti-NF-κB	Zhu et al., 2012
NaHS (150 μmol/kg, i.p., 30 min prior to ischemia)	I (1 h)/R (2 h); warm ischemia	Lewis rat	Improved renal function; reduced renal injury	Anti-inflammation	Bos et al., 2013
Na ₂ S (i.v.; a bolus of 100 μg/kg was given 10 min before reperfusion, followed by an infusion of 1 mg/kg given continuously for 30 min after reperfusion)	I (1 h)/R (7 days)	Large white pig	Improved renal function; reduced renal injury	Anti-inflammation	Azizi et al., 2015
NaHS (75 μmol/kg; i.p.; 10 min prior to ischemia and immediately before reperfusion)	I (55 min)/R (24 h)	Wistar rat	Improved renal function; reduced renal injury	Anti-apoptosis; anti-oxidation	Han et al., 2015
AP39 (0.3 mg/kg; i.p.; 5 min before reperfusion)	I (30 min)/R (24 h)	Sprague-Dawley rat	Improved renal function; reduced renal injury	Anti-apoptosis; anti-oxidation	Ahmad et al., 2016

i.p., intraperitoneal; *i.v.*, intravenous; *I/R*, ischemia/reperfusion; *MAPK*, mitogen-activated protein kinase.

H₂S in Diabetic Nephropathy

Diabetic nephropathy is the number one leading cause of CKD in western countries. Morphologically, DN is characterized by hypertrophy induced kidney growth and excessive accumulation of extracellular matrix proteins, eventually proceeding to fibrosis of glomerular and tubulointerstitial compartments (Cooper, 1998; Dronavalli et al., 2008). Current evidence suggests an active role of H₂S in the pathogenesis of DN. Plasma H₂S level in

DN patients is significantly lower than that in non-DN patients undergoing chronic hemodialysis (Li et al., 2014). High urinary sulfate concentration, a reflection of high plasma H₂S level, is associated with reduced risk of renal disease progression in type 2 diabetes (van den Born et al., 2016) and slower decline in Cr⁵¹-EDTA-assessed GFR in DN patients (Andresdottir et al., 2013). Recent data suggested that the renal expression of H₂S producing enzyme CBS and CSE is down-regulated in pancreatic CaMTg

diabetic mice (Yamamoto et al., 2013), C57BL/KsJ *lepr^{-/-}* db/db mice (Lee et al., 2012), STZ-diabetic rats (Yuan et al., 2011), and Akita diabetic mice (Kundu et al., 2013). Inhibition of CSE with PAG mimics high glucose-induced glomerular podocyte injury (Liu et al., 2015), implying a contributive role of endogenous H₂S in DN. The mechanisms underlying CBS and CSE reduction have been also studied. Kundu et al. (2013) showed that MMP-9 was upregulated in Akita diabetic mice along with the reduction of CBS and CSE. When MMP-9 is knocked out, the expression of the two H₂S producing enzyme namely CSE and CBS shows a trend toward baseline despite hyperglycemia (Kundu et al., 2013) suggesting that MMP-9 regulates CBS and CSE expression in DN (Figure 3A).

Meanwhile, exogenous H₂S has been proved to be effective in *in vitro* and *in vivo* DN models. High glucose caused cell proliferation and collagen formation are attenuated by NaHS in cultured mesangial cells (Yuan et al., 2011) and tubular cells (Safar and Abdelsalam, 2015). Moreover, NaHS alone (Yuan et al., 2011; Ahmad et al., 2012; Lee et al., 2012; Kundu et al., 2013; Xue et al., 2013; Zhou et al., 2014; Liu et al., 2015; Safar and Abdelsalam, 2015; Qian et al., 2016) or with losartan (Kaur et al., 2015) ameliorates renal dysfunction and fibrosis formation in

various DN related animal models. At least three mechanisms (Figure 3B) are implicated in H₂S mediated protective effect in DN: (1) Inhibition of ROS formation by activating Nrf2 pathway. Hyperglycemia induces intracellular ROS which upregulates the expression of MMP-9 (Kundu et al., 2013). MMP-9 plays a major role in diabetic renovascular remodeling. In a STZ induced diabetic rat model, H₂S was found to reduce high glucose induced oxidative stress by activating the Nrf2 antioxidant pathway and thereby the level of MMP-9 (Zhou et al., 2014); (2) AMPK activation. Matrix protein deposition requires stimulation of protein synthesis. In DN, PI3K/Akt/mTORC1 signaling is activated due to the suppression of AMPK activity (Yuzawa, 2012). The inactivation of AMPK was found to be partially ascribed to the reduction of H₂S level (Lee et al., 2012). NaHS dose- and time- dependently activates the phosphorylation of AMPK and inhibits the stimulation of mTOR (Lee et al., 2012). As a result, mTOR mediated protein synthesis is inhibited which partially accounts for the protective effect of H₂S in DN. (3) Stimulation of NO formation. Hyperglycemia upregulates NOX4 expression resulting in the generation of intracellular ROS and laminin γ 1, both of which contribute to renovascular remodeling (Gorin et al., 2015). Expression of NOX4 can be attenuated by

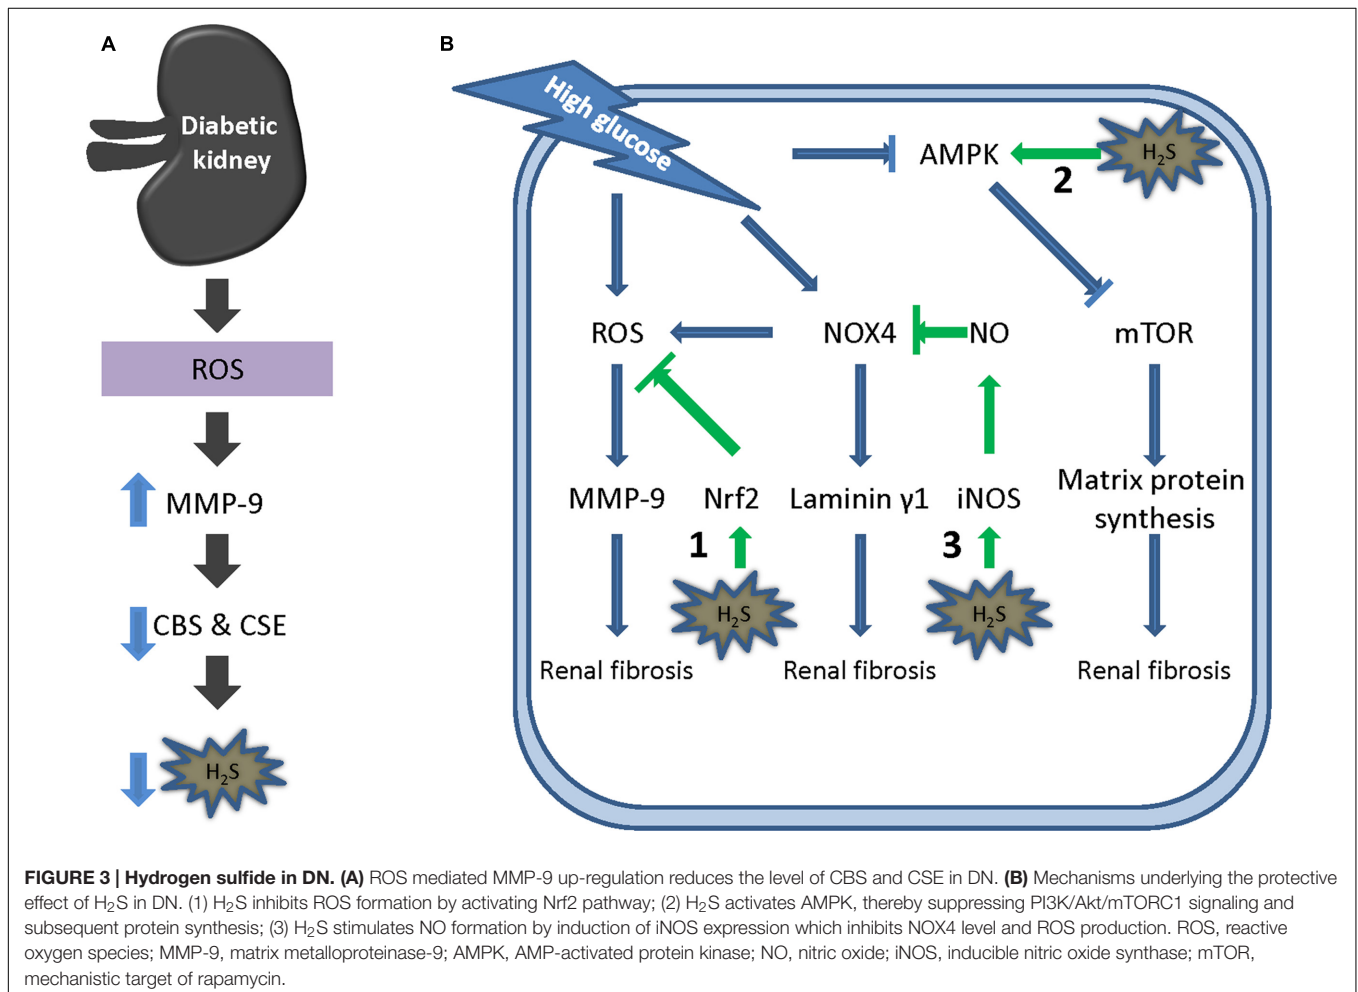

FIGURE 3 | Hydrogen sulfide in DN. (A) ROS mediated MMP-9 up-regulation reduces the level of CBS and CSE in DN. **(B)** Mechanisms underlying the protective effect of H₂S in DN. (1) H₂S inhibits ROS formation by activating Nrf2 pathway; (2) H₂S activates AMPK, thereby suppressing PI3K/Akt/mTORC1 signaling and subsequent protein synthesis; (3) H₂S stimulates NO formation by induction of iNOS expression which inhibits NOX4 level and ROS production. ROS, reactive oxygen species; MMP-9, matrix metalloproteinase-9; AMPK, AMP-activated protein kinase; NO, nitric oxide; iNOS, inducible nitric oxide synthase; mTOR, mechanistic target of rapamycin.

H₂S (Kamat et al., 2015). L-NAME, a NOS inhibitor, abolished the effect of H₂S (Feliars et al., 2016). Further study showed that H₂S upregulates the protein expression of iNOS but not that of eNOS (Feliars et al., 2016). Moreover, iNOS siRNA can block the effect of H₂S (Feliars et al., 2016) suggesting a role for NO in H₂S mediated protective effect in DN. Interestingly, NO can also stimulate the activity of CSE and H₂S production (Nagpure and Bian, 2016) suggesting a cross-talk interaction between these two pathways.

H₂S in Hypertensive Nephropathy

Hypertensive nephropathy, a result of chronic hypertension, is the second leading cause of CKD worldwide (Hart and Bakris, 2010). Long time of high BP load results in damages of kidney, especially in glomerulus. When kidney cannot function properly, it fails to regulate BP. In turn, BP will rise up which further aggravates renal damage (Bidani and Griffin, 2004). Extensive evidence suggests a role of H₂S in BP control. Genetic deletion of CSE causes hypertension and diminished endothelium dependent vasorelaxation (Yang et al., 2008). Similar with this, inhibition of both CBS and CSE also increases BP in rat (Roy et al., 2012). These data implies that H₂S is a physiologic regulator of BP. Further studies suggest that H₂S functions as both an EDHF (Mustafa et al., 2011; Edwards et al., 2012; Tang et al., 2013) and an EDRF (Wang, 2009). The BP lowering effect of exogenous H₂S has been subsequently determined. Our group first showed that H₂S donor, NaHS, attenuated BP by inhibiting plasma renin activity in a 2K1C rat model (Lu et al., 2010). Thereafter, NaHS was demonstrated to reduce BP in spontaneous hypertensive rats (Ahmad et al., 2014), angiotensin II treated mice (Al-Magableh et al., 2015), and sFlt transgenic mice (Holwerda et al., 2014). Additionally, renal protective effects of H₂S have also been reported in hypertensive nephropathy. sFlt overexpression in mouse results in hypertension with proteinuria and glomerular endotheliosis, all of which are apparently attenuated by administration of NaHS (Holwerda et al., 2014). Further study suggests an involvement of VEGF in this H₂S mediated effect (Holwerda et al., 2014). Both H₂S and tempol were found to alleviate renal dysfunction in a spontaneous hypertensive rat model by suppressing ROS formation (Ahmad et al., 2014). Recently, Jin's group reported that either NaHS or its metabolite sodium thiosulfate attenuated angiotensin II induced proteinuria, renal dysfunction, and structural deterioration in rat (Al-Magableh et al., 2015). Further studies suggested that the renal effects of H₂S were partially mediated by suppression of epithelial sodium channel (Zhang et al., 2013; Wang et al., 2015). Taken together, H₂S might be an ideal candidate for the treatment of hypertensive nephropathy.

FUTURE DIRECTIONS

Role of Mitochondrial H₂S Pathway in Kidney Diseases

In contrast to the extensive studies on CBS and CSE in various kidney diseases, the role of 3-MST is largely neglected although definitive evidence has demonstrated its abundance

in kidney (Aminzadeh and Vaziri, 2012; Shibuya et al., 2013; Kimura, 2014). 3-MST resides in mitochondria and is the major producer of mitochondria derived H₂S. 3-MST silencing was reported to reduce bioenergetic parameters and H₂S can serve as an electron donor in mammalian cells (Modis et al., 2013), indicating a possible physiological role of 3-MST/H₂S pathway in maintaining mitochondrial electron transport and cellular bioenergetics. Renal ischemia is the most common cause of acute kidney injury. Hypoxia leads to the inhibition of mitochondrial respiratory chain by deprivation of O₂. What will happen if H₂S is supplemented into the mitochondria when hypoxia occurs? Szabo's group (Ahmad et al., 2016) showed that mitochondrially targeted H₂S donor AP39 ameliorated renal damage in an ischemia/reperfusion rat model, suggesting possible involvement of 3-MST/H₂S pathway in the pathogenesis although the change of 3-MST level and activity upon hypoxia was not determined. Additionally, the importance of 3-MST/H₂S pathway is also suggested by the fact that ROS, the common cause of renal diseases of all types, induces the translocation of CBS and CSE into mitochondria (Fu et al., 2012). Thus, the revelation of the involvement of 3-MST in kidney diseases is of great value.

Targeting DAO/3-MST Pathway for H₂S Delivery to Kidney

Safety is always a concern when administrating H₂S systemically due to its well-known toxicity (Guidotti, 2010; Hirose, 2010) which might hamper its development as therapeutics. This safety issue might be diminished by specific delivery of H₂S to the targeted organs. Unfortunately, such organ specific H₂S donor is not reported. The discovery of DAO/3-MST pathway might provide a clue about how to deliver H₂S specifically into the kidney. The pathway uniquely utilizes D-cysteine rather than L-cysteine to produce H₂S and exclusively exists in cerebellum and kidney (Shibuya et al., 2013). When D-cysteine is given, it attenuates IRI in kidney with higher potency than L-cysteine (Shibuya et al., 2013). As H₂S is broadly renal protective as we have reviewed above, D-cysteine might also ameliorate other renal diseases. Direct administration of D-cysteine induces the generation of H₂S in both cerebellum and kidney (Shibuya et al., 2013). Nevertheless, it is possible that structural modification of D-cysteine can generate a novel moiety providing D-cysteine to kidney but not cerebellum due to the impermeability of blood-brain barrier. This hypothesis warrants further investigation.

Test of Drug-Like H₂S Donors in Kidney Disease

To date, most studies of H₂S effect in kidney have been largely restricted to the use of NaHS as an H₂S donor despite of rare exceptions with GYY4137 or AP39. However, NaHS releases H₂S at an uncontrolled manner (Li et al., 2008) and is unlikely to be a therapeutic agent (Szabo, 2007). Numerous drug-like H₂S donors have been developed and some of them are under the investigation in clinical trials. For instance, an orally active H₂S donor SG-1002 is proven to be safe in humans and underwent Phase II study for heart failure (ClinicalTrials.gov identifier: NCT01989208); Antibe Therapeutics are conducting several

preclinical or clinical studies with their various H₂S donors (ATB-346 for osteoarthritis; ATB-352 for Acute pain; ATB-350 for Thrombosis). The information on these H₂S releasing donors can be found in Wallace and Wang (2015). Testing of these drug-like H₂S donors will not only consolidate the protective effect of H₂S, but also shed light on the translation of H₂S as a therapeutic agent for renal diseases.

Understanding the Molecular Mechanism of H₂S

Last, but not least, one should bear in mind that the molecular mechanisms underlying H₂S effect is still not well-understood. It seems that H₂S may partially exert its effect as a reducing agent to eliminate ROS (Bruce King, 2013), while its effects on gene expression may be related to specific molecular targets like NF- κ B and the ERK pathways (Oh et al., 2006). However, the molecular details are still unclear. Thus, the in-depth portrayal about the interaction between H₂S and its target protein will be interesting.

CONCLUSION

After recognition as the third gaseous mediator after NO and CO, the biological actions of H₂S are still expanding. In kidney, it

is actively participating in the renal regulation in physiological condition. Due to the regulatory role of kidney in the body, it is possible that H₂S has far-reaching actions by modulating renal function which needs to be uncovered. Because of the significant role of H₂S in renal physiology, it is not surprising that dysfunction of H₂S contributes to the pathogenesis of kidney related diseases. Thereafter, administration of H₂S mainly with NaHS was proven to rescue kidney damages in animal models with various types of kidney diseases. In the future, drug like H₂S donors need to be tested to translate H₂S as a treatment for renal diseases in clinical. Besides, in-depth studies of H₂S mediated molecular actions are also needed to complete our understanding of the role of H₂S in both renal physiology and pathology.
