2NOTICE

The invention disclosed in this document resulted from research in aeronautical and space activities performed under programs of the National Aeronautics and Space Administration. The invention is owned by NASA and is, therefore, available for licensing in accordance with the NASA Patent Licensing Regulation (14 Code of Federal Regulations 1245.2).

98

To encourage commercial utilization of NASA-owned inventions, it is NASA policy to grant licenses to commercial concerns. Although NASA encourages nonexclusive licensing to promote competition and achieve the widest possible utilization, NASA will consider the granting of a limited exclusive license, pursuant to the NASA Patent Licensing Regulations, when such a license will provide the necessary incentive to the licensee to achieve early practical application of the invention.

Address inquiries and all applications for license for this invention to NASA Patent Counsel, Langley Research Center, Mail Code 279, Langley Station, Hampton, VA 23665. Approved NASA forms for application for nonexclusive or exclusive license are available from the above address.

AWARDS ABSTRACT

NASA CASE NO. LAR 14203-1

METHOD AND CIRCUIT FOR SHAPING LASER OUTPUT PULSES

The invention is a novel method and circuit for shaping laser output pulses from a laser resonator by sensing and utilizing a portion of a laser output pulse to produce a control signal used to control the length and thus shape of the resulting laser output pulse by varying the loss of a Q-switch in the laser resonator. The invention is expected to find governmental and other commercial application.

METHOD AND CIRCUIT FOR SHAPING LASER OUTPUT PULSES

Cross-Reference to Related Applications

5 This application is related to copending application serial number _____, filed _____, 1989 entitled "Method and Circuit for Controlling the Evolution Time Interval of a Laser Output Pulse" (NASA Case No. LAR 13772-1).

10 Background of the Invention1. Field of the Invention

The invention is a method and circuit for shaping laser output pulses and more particularly from a Q-switched laser device.

15

2. Description of the Prior Art

It is known to produce a high energy laser output having a long pulselength using a low energy laser oscillator that undergoes relaxation oscillations. While this method works, it is not very efficient. Essentially, only
20 the energy in one of the relaxation oscillations is utilized while the rest is discarded. Other known methods such as the use of a conventional normal mode laser and an electro-optic switching system to slice out only a portion of the resulting pulse have proven to be even less efficient and less repeatable.

25 Object and Summary of the Invention

An object of the invention is to overcome the limitations of the prior art by providing a novel method and circuit for producing laser energy more efficiently and with a shaped or controlled output pulse length.

30

Brief Description of the Drawings

FIG. 1 illustrates a prior art method and circuit for achieving a long
pulselength in a laser pumping device including a low energy oscillator which
5 undergoes relaxation oscillations; and

FIG. 2 illustrates a schematic of a preferred embodiment of the invention
including an electro-optic element for producing long laser output pulses from
a Q-switched laser device.

10 Brief Description of the Invention

Referring to the drawing, FIG. 1 represents a prior art laser resonator as
generally designated by reference numeral 10 as including a totally reflecting
mirror 11, an active or laser medium 12 such as to provide gain, a polarizer
13, an electro-optic switch 14, and a second partial reflector or mirror 15. In
15 operation while the active laser medium 12 is being excited, the electro-optic
switch or Q-switch 14 is adjusted so that any radiation entering the portion of
the laser resonator which contains the Q-switch will undergo a change from
linear polarization to circular polarization on the first pass. On the return
20 pass, the circular polarization is converted to orthogonally polarized radiation
that is reflected by the polarizer 13. Thus, with the switch 20 closed there is
no feedback and laser oscillation (voltage 14 applied) will not take place.

In the operation of conventional prior art resonator 10, a pump source
such as a flash lamp 16 excites the active laser medium 12. In this excited
25 condition any photon simultaneously emitted along the axis 17 may cause
laser action. However, in this configuration the polarizer 13 and Q-switch 14
acting in combination prevent laser action permitting only radiation polarized
along a particular axis to pass through the polarizer 13. The resulting linearly
polarized radiation that passes through the polarizer 13 is converted to
30 circularly polarized radiation in passing through the Q-switch 14 when
activated by a suitable voltage 19 by closing switch 20. Some of this
circularly polarized radiation is reflected by the partial reflector mirror 15 back

through the Q-switch 14 in the reverse direction and converted to orthogonally polarized linear radiation which is rejected by the polarizer 13. Thus, no feedback results and no laser oscillation or action occurs.

By deactivating the Q-switch 14 (removing the voltage 19 by opening
5 switch 20) the described conversion of the polarization in the electro-optic switch 14 no longer occurs and laser oscillation or action starts and the resulting laser output pulse 18 is extracted through the partial mirror 15. The length of the resulting output pulse 17 is determined essentially by the photon lifetime of the resonator 10 and the number of times over threshold as is
10 known.

In accordance with a preferred embodiment of the invention as shown in FIG. 2, the action of a Q-switch 14' is controlled to provide a laser output 17' having a selectively variable output pulse length. As in the prior art circuit, during excitation of an active laser medium 12' there is no feedback of optical
15 radiation in the resonator 10' formed by a total mirror 11' and a total mirror 15' which replaces the partial mirror 15 in FIG. 1. In the preferred configuration shown in FIG. 2, a quarterwave plate 18' also acts like a constantly activated Q-switch such as Q-switch 14'. Thus, when laser oscillation is desired a selected variable switching voltage 19' applied to
20 Q-switch 14' negates part or all of the effect of the quarterwave plate 18' depending upon the amount of applied switching voltage 19'. Radiation rejected by the polarizer 13' passes through reflector 21' as a laser output pulse 17'. This is in contrast to FIG. 1 in which the laser output pulse 17 comes from the partial mirror 15.

25 While the conventional Q-switch 14 is activated or fully switched on or off by a full quarterwave voltage, a full quarterwave voltage 19' is not applied to the Q-switch 14' initially in accordance with the invention. Instead, it is applied over the duration d of pulse 17'.

In practicing the method, sufficient voltage 19' is initially applied to the Q-
30 switch 14' to sustain laser oscillation at a low level. As the active laser medium 12' is depleted and the optical gain decreased, the voltage 19' applied to the Q-switch 14' increases due to the action of amplifier 24'. This

provides more feedback and laser oscillation continues at a reduced optical gain level. As the optical gain decreases further, the voltage 19' is increased further and therefore the level of feedback output 23' is also increased to maintain laser output pulse 17' at a constant level. This action provides the
5 desired controlled and longer pulse length d of the output pulse 17' which varies linearly with the power of that portion of the output pulse 17' received by photodiode 22', the output 23' of which is amplified by amplifier 24'. The gain of the amplifier 24' is adjusted so that the negative output 26' offsets the positive voltage 27' providing a variable positive output pulse 19' which
10 activates Q-switch 14' and thus output pulse 17'. The 19' varies over the duration of pulse 17' to maintain a constant output pulse 17'.

As shown in FIG. 2, the desired and controlled switching voltage 19' for operating the Q-switch 14' is applied from a conventional amplifier 21' to initiate and maintain laser oscillation. As this laser action continues, part of
15 the resulting laser output signal 17' is detected by a suitable photodiode 22', the output 23' of which is amplified by a conventional amplifier 24' the output 26' of which is applied to the negative pin of the differential amplifier 21'. The positive voltage 19' required to initiate laser oscillations is applied to the Q-switch 14' through the differential amplifier is from a suitable battery 27'
20 connected to ground 28' and to the positive pin of differential amplifier 21' through a suitable control switch 29'. If the level of the laser output 17' becomes too large, the positive voltage 19' applied to the Q-switch 14' to facilitate laser oscillation is negated by the amplified laser output 26'. By negating the applied positive voltage, the resonator provides less feedback
25 which reduces the laser output 17'. As the optical gain decreases, the level of the laser output 17' also tends to decrease. This, in turn, provides less negative feedback 26', which tends to increase the optical feedback in the resonator. Thus the laser action tends to increase. Through proper adjustment of the operating parameters of the feedback system, such as the
30 initial setting of voltage 27' and the gain of the amplifier 24', the duration d or length of laser output pulse 17'.

While a preferred and alternative embodiments have been described in detail, numerous changes and modifications may be made without departing from the invention which is to be limited only by the appended claims.

What is claimed is:

5

METHOD AND CIRCUIT FOR SHAPING LASER OUTPUT PULSES

Abstract of the Disclosure

5 The invention is a method and circuit for shaping laser pulses 17' in which
a laser medium 12' in a laser resonator 10' that includes a Q-switch 14' and
polarizer 13' which act in combination to control the loss of the resonator 10'
and provide the laser output 17' representative of such loss. An optical diode
22' senses the level of the output pulse 17' and provides an output signal 23'
10 that when amplified is used with a control voltage from a supply 29' to provide
a control signal 19' which is applied to Q-switch 14' to control the shape of
the output pulse 17' by adjusting its length.
