FOREWORD

This document represents the final technical report on JPL Contract 952028, A Study Program on the Development of Mathematical Model(s) for Microbial Burden Prediction. This report was prepared in accordance with the requirements established by the subject contract. The final report is submitted in three (3) volumes:

Volume I	Technical Report
Volume II	User's Manual for the Microbial Burden Prediction Program
Volume III	Appendices

APPENDIX I

Appendix I contains a summary of assumptions made during the development of the burden prediction model. These assumptions are:

1. Within the context of planetary launch vehicles as they are currently conceived or forecast, any such vehicle will require a probe system.
2. Such a probe system will include, but not be limited to, the following major systems:
 - a. Lander or Surface Module
 - b. Entry Package
 - c. Deorbit Module
 - d. Canister
 - e. Adapter
3. The probe systems will be manufactured, assembled and Flight Acceptance Tested (as defined by specification) by either the probe Prime Contractor or a Sub-contractor.
4. The assembly and test of such a probe will take place at two (2) locations, the Prime Contractor's Facility and the mission launch site (nominally ETR).
5. Periodic assays of the probe hardware may be made during the assembly and test sequence.

APPENDIX I (Continued)

6. Normal assembly will take place in a Class 100 clean room environment; test operations will take place in a Class 100 or dirtier environment.
7. In "Clean" areas, environment and personnel access will be controlled and, to some degree, monitored on a periodic basis.
8. The sample size of the sum (product, etc.) of two distributions is at least equal to the smaller of the two sample sizes. (A considerable savings in assay work is likely to result if the exact relationship can be determined).
9. The sensitivity of the output to a given parameter can be multiplied by the desired output sample size to get an approximation for the sample size of the parameter. (Again, a savings in assay work is likely to result if the exact relationship can be determined.)
10. In order to simulate the "plateau" phenomenon, it was necessary to assume that organisms remain (alive) on a given surface a certain average length of time and then are (somehow) lost. A value of 100 hours seems approximately correct for exposed surfaces, but no data could be found for mated and occluded surfaces. The latter was assumed to be 1000 hours.

APPENDIX I (Continued)

11. A first-order model was assumed for the fallout-“die-off” process on surfaces:

$$B' = B e^{-t/v} + AvR (1 - e^{-t/v})$$

12. The formula for fallout rate ($R = f_1 g c$) has some experimental verification (Ref. 34), but may not be appropriate in all circumstances.
13. The fallout velocity (f_1) is assumed constant in a given environment, and is otherwise assumed to be a well-defined measurable quantity.
14. It is assumed that a meaningful value can be assigned to the local increase in airborne concentration of organisms due to the (transient) presence of people or equipment. In this relation, the concentration is assumed to decrease exponentially, with distance from the source: $c = Qe^{-\lambda d}$, where λ is an undetermined factor.
15. Burden transfer by contact is assumed to be represented by the formula:

$$B' = B - \frac{S_2 a}{2A} B + \frac{S_1 a}{2} b_t$$

This model assumes that the surface retention factors S_1 and S_2 can be assigned to surfaces instead of pairs of surfaces (i.e., the interaction is negligible).

APPENDIX I (Continued)

16. The computer program accounts for contact at the end of an operation even though the contact may actually have occurred at intervals throughout the operation. It is assumed that this difference is negligible. (If not, the operation can easily be separated into shorter operations).
17. Contact is assumed to occur almost instantaneously.
18. It is assumed that merely keeping track of the total burden on each surface of each part (or zone) is sufficient; this burden is then considered uniformly distributed over that surface. (The zones must be chosen so small that this is acceptable.)

APPENDIX II.

Appendix II contains a summary of reference documents used during the development of the microbial burden prediction model. These documents were identified from the literature search and from the functional analyses performed on the Capsule Bus System.

APPENDIX III

Capsule Bus System Functional Analyses

Appendix III contains the results of all functional analyses performed on the Capsule Bus System, during the burden prediction model development program. These results are presented in two (2) different formats to facilitate their use. The formats used are tabular presentation and flow charts.

Appendix III is divided into two (2) sections. Section 1 contains the FIRST and SECOND levels of activity identified from the generalized Capsule Bus System Assembly and Test Sequence.

Section 2 contains a description of all four (4) levels of activity which must be performed to assemble and test the Capsule Bus System; these data are presented in tabular form and they describe the work performed at each level.

A. Section 1 - Operational Analyses for the Flight Capsule Assembly
and Test (FIRST and SECOND Levels)

Section 1 contains the FIRST and SECOND levels of activity identified from the generalized Capsule Bus System Assembly and Test Sequence. FIRST level activity is presented in Table III.1; SECOND level activity is presented in Table III.2. In addition, Section 1 contains the FIRST and SECOND levels of activity, in flow chart form. FIRST level activity is presented in Figure III.1; SECOND level activity is presented in Figure III.2.

B. Section 2 - Capsule Bus System Detailed Functional Analysis

Section 2 contains a tabular description of four (4) levels of activity which must be performed to assemble and test the Capsule Bus System. These data are presented in tabular form and they describe the work performed at each level. In addition to identifying the levels of activity, the results of the functional analysis reflect several other considerations which are important in the assembly and testing of the Capsule Bus System. These considerations involve the identification of work location (i.e., Pasadena), major module (i.e., Vernier Module), hardware (i.e., Vernier Structure) and the subsystem being operated upon (i.e., Structure and Mechanisms).

In the front of the table, prior to the assembly and test sequence proper, each activity level and assembly consideration is identified. Identification is done by numeric, alpha or alpha-numeric codes. These precise codes are used in the assembly and test sequence description and, once assigned, their meaning does not change.

In order to make it possible to identify any of the four (4) activity levels and the associated considerations (subsystem, hardware, etc.), an indenture system was adopted. Each of the eight (8) indenture levels identifies an activity level or one of the considerations associated with the assembly and test sequence. For instance, in Table III.3, indenture level 1 identifies the site at which the work is being performed. Indenture level 2 identifies the FIRST level of activity in the Capsule Bus System general sequence. Indenture level 3 identifies the module being assembled. Indenture level 4 identifies the subsystem on which work is being performed. Indenture level 5

the hardware which is being used in the module assembly. Indenture levels 6-8 identify the SECOND, THIRD and FOURTH Levels of activity identified from the general sequence. Adherence to this indenture system makes it possible, at any point in the assembly and test sequence, to determine activity level, work location, the major module, the subsystem and the hardware which are involved.
