FOREWORD

The study was conducted at the Dayton Laboratory of the Monsanto Research Corporation, Dayton, Ohio, under Contract No. F33615-67-C-1357. The principal investigator was Mr. F. Neil Hodgson for the Monsanto Research Corporation. The study was started in January 1967 and was completed in February 1968. The entire study was under the project leadership of Mr. John V. Pustinger, Jr., of Monsanto Research Corporation.

This research was initiated by the Chemical Hazards Branch, Toxic Hazards Division, Biomedical Laboratory in support of Project 6302, "Toxic Hazards of Propellants and Materials," Task 630204, "Environmental Pollution." Mr. Solomon Brokeshoulder and Dr. Gerd A. Kleineberg of the Chemical Hazards Branch were contract monitors for the Aerospace Medical Research Laboratories.

The authors acknowledge the invaluable assistance of Mr. Bruce E. Boggs, Mr. Donald Q. Douglas, and Mr. John E. Strobel; all of Monsanto Research Corporation.

This technical report has been reviewed and is approved.

WAYNE H. McCANDLTSS

ABSTRACT

Fifty-three candidate materials for space cabin construction were tested to establish volatile gas-off and oxidation products. Testing was accomplished by two methods:

- (a) preliminary screening by thermogravimetric analysis to determine weight loss during 24 hours at 25°C to 68°C in a nitrogen atmosphere at 5 psia.
- (b) storage tests at 68°C for 72 hours and at 25°C for 30 and 60 days in oxygen at 5 psia, followed by analyses of the chamber gases.

The preliminary screening by measuring weight loss was to determine those materials which exhibit weight losses between 0.001% and 1.0%, exclusive of water. Materials falling within this range were studied further in storage tests to determine the nature of the individual components evolved from the candidate material. Those materials falling outside this range were conditionally excluded from further tests. Weight loss data, thermogravimetric curves, gas chromatograms of volatile contaminants, and the nature and quantities of individual components evolved from the candidate materials are reported.

In addition to the gas-off experiments, gas chromatographic and mass spectrometric analyses were performed on 7 samples of atmospheres from bio-environmental systems.

SECTION I

INTRODUCTION

Previous material evaluation programs^{1,2} have shown that certain candidate space cabin materials, when tested under simulated space cabin environmental conditions (5 psia oxygen or air at 25°C or 68°C), yield an abundance of volatile contaminants to the atmosphere. In these programs, storage systems and analytical methods had been devised to identify and to measure quantitatively the gas-off products in the gas phase. As a continuation of these studies, an evaluation program, based on weight-loss measurements and on the storage tests and attendant analyses used previously, has been developed for screening 53 candidate space cabin materials.

Storage tests and subsequent analyses of the gases in the chamber atmosphere are time-consuming. An initial screening of the materials is desirable to discover the materials that give an abundance of volatile contaminants, and those that yield practically none. On this basis, materials could be selected for further testing or conditionally eliminated from additional tests. Materials giving moderate amounts of contamination would be tested further to identify and to measure individual contaminants.

The merit in the use of weight-loss measurements is the comparative simplicity of the equipment and the relatively short measurement time. The intrinsic limitation of this approach is the inability to identify directly the evolved products. On the other hand, the advantage of closed chamber storage tests is the ease with which identification and quantitative analyses of the head gases can be performed; however, the disadvantages are the time-consuming processes of storing specimens for long periods and of performing the identifications of the volatiles. Our program was developed to take advantage of the best characteristics of both approaches.

Pustinger, J. V., Hodgson, F. N., Ross, W. D., 1966, Identification of Volatile Contaminants of Space Cabin Materials, AMRL-TR-66-53, Aerospace Medical Research Laboratories, Wright-Patterson Air Force Base, Ohio, pp. XVI + 194.

²Pustinger, J. V., Hodgson, F. N., 1967, Identification of Volatile Contaminants of Space Cabin Materials, AMRL-TR-67-58, Aerospace Medical Research Laboratories, Wright-Patterson Air Force Base, Ohio, pp. XVI + 194

The initial screening procedure, using thermogravimetric techniques for measuring weight loss at moderate temperatures (ambient to $68 \pm 2^{\circ}\text{C}$) for 24 hours in 5 psia nitrogen, was developed to select those candidate materials that lose from 0.001 to 1.0% of their weight, excluding water. The selected materials are then stored in 9-liter chambers at $68 \pm 2^{\circ}\text{C}$ for 72 hours and at 25 \pm 2°C for periods of 30 and 60 days. Atmosphere in the chambers is oxygen at a pressure of 5 psia. The gaseous contaminants evolved from the test materials are identified by combinations of gas chromatography and mass spectrometry.

SECTION II

GAS-OFF EXPERIMENTS

A. EXPERIMENTAL METHOD

1. Types of Candidate Materials and Sample Preparation

Table I lists the candidate materials for cabin construction used in these experiments; all materials tested are commercial products provided by the Government. Whenever possible, the candidate materials were studied in the same state as received. Materials such as paints and inks were applied to an aluminum foil substrate and then dried at the designated temperature and for the designated time according to the manufacturer's or the Air Force's directions. Similarly, two-part resins were mixed and cured according to procedures provided by the manufacturers. All calculations were made on the basis of dry sample weight.

Specimens used for thermogravimetric analysis (TGA) were conditioned at 23°C in a desiccator over phosphorus pentoxide for 24 hours prior to testing. For storage tests at 72 hours, 30 days, and 60 days, no pretreatment of samples was performed beyond the curing procedures cited by the manufacturers or the Air Force. The procedure for preconditioning the TGA specimens was devised to minimize adsorbed water and to put all samples on the same basis for comparing relative weight loss.

For storage tests for 72 hours, 30 days, and 60 days, a weighed portion of each sample was placed into a 9-liter chamber in a manner to expose the largest possible surface area. Generally, approximately 10-gram specimens were used; however, in cases where less sample was available, or when the bulk volume of the sample was excessively large, smaller specimens were used. When the bulk volume was too large and subdividing was necessary, freshly exposed surfaces were further cured at ambient conditions, i.e., 23°C and atmospheric air pressure, for 30 days or a minimum of 14 days.

Individual specimens of each candidate material were contained in 9-liter, borosilicate glass chambers for periods of 30 and 60 days at 25 \pm 3°C, and for a period of 72 hours at 68 \pm 2°C, under an oxygen atmosphere at 5 psia and 20-40% relative humidity. The chamber design and pretreatment of the chambers were the same as reported earlier. Two-hundred chambers were used (on a staggered schedule) over a span of 13 months to permit analyses to be performed after 72 hours,

THE PROPERTY OF

30 and 60 days. Control chambers (containing only aluminum foil) were processed concurrently with those chambers containing the test materials. No contamination was detected from the control chambers.

2. Preparation of Chamber Atmospheres

After each specimen was inserted into the 9-liter chamber, the test chamber was filled to a pressure of one atmosphere with oxygen, saturated with water vapor. The gas was saturated with water by bubbling 99.5% oxygen (conforming to Type I of MIL-0-27210) through triply distilled water at 23°C. Test conditions were attained by subsequently reducing the pressure in the chamber to 5 psia, resulting in a test atmosphere of oxygen at 5 psia with a relative humidity of approximately 33%.

Measurement of relative humidity was made with an Alnor Type 7300 Dew-Pointer (Illinois Testing Laboratories, Inc., Chicago, Ill.).

Test atmospheres were maintained at $25 \pm 3^{\circ}\text{C}$ by storing chambers in a temperature-controlled room for periods of 30 and 60 days. The chambers that were tested at $68 \pm 2^{\circ}\text{C}$ were stored in a constant-temperature cabinet (Blue M Electric Co., Stabil-Therm DL132C).

3. Analytical Methods

a. Weight Loss Measurements

Conditional screening of candidate materials was performed by measuring the weight loss of the material using thermogravimetric measurements (TGA). Weight loss from approximately 10 g of a material was recorded continuously as the temperature of its environment was raised from ambient (approximately 23°C) to $68 \pm 1^{\circ}\text{C}$ in 4 hours and then maintained at $68 \pm 1^{\circ}\text{C}$ for 20 hours or until weight remained constant for 2 hours. All TGA measurements were made in dried, prepurified nitrogen at 5 psia.

Thermogravimetric measurements were made with a Cahn RH Electrobalance equipped with a modified F&M Model 240-00 Power Proportioning Temperature Programmer, Flo-Thru tube, a temperature programmed oil bath, and a 1 mv recorder (Figures 1, 2, and 3). The Cahn RH Electrobalance is a vacuum- and controlled-atmosphere automatic recording balance with 100-gram capacity

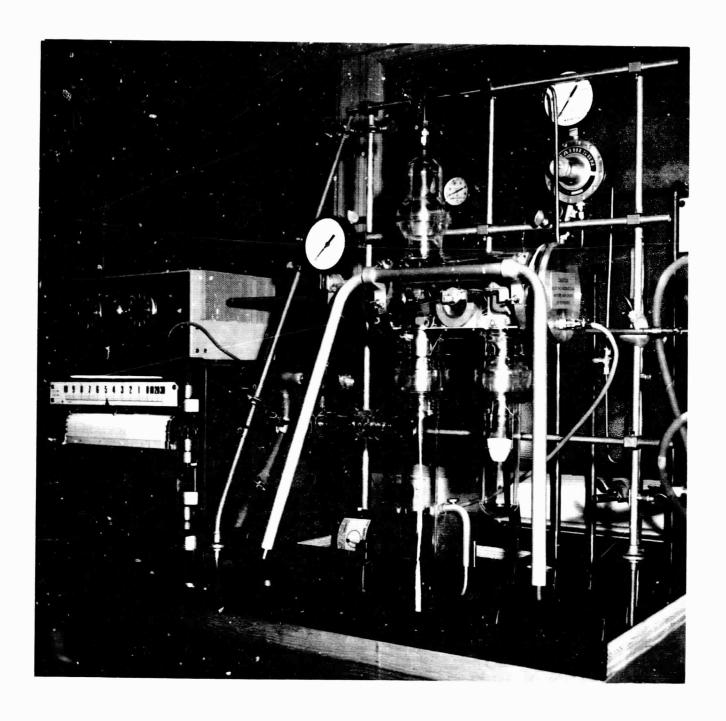

Figure 3. Complete TGA System.

and a sensitivity of 10^{-6} g. This thermogravimetric system will permit the handling of relatively large specimens, 1-10 grams, and the detection of small weight changes, a 10^{-7} fraction of the load.

The arrangement of the components of the TGA system is shown in Figures 1, 2, and 3. To permit greater control and more uniform heating, the sample is heated with an oil bath rather than an oven or furnace. The slow heating rate of one degree every six minutes is more easily achieved by adjusting the temperature of the oil bath than by using a heating unit directly. The temperature was programmed with an F&M Power Proportioning Temperature Programmer that had been modified to permit the slow heating rate.

Water evolved from the sample was monitored by either of two gas chromatographic methods:

- (a) by converting the water to acetylene by a reaction with calcium carbide and analyzing for acetylene;
- (b) by cryogenically trapping the desorbed water and subsequently performing a direct measurement for water.

Gas chromatographic analyses for acetylene were performed with a flame ionization detector (F&M 1609) and a Porapak T column, whereas direct gas chromatographic measurements for water were performed with a thermal conductivity detector (Barber-Colman 61C) and a Porapak T column.

b. Gas Chromatographic Analysis of Gas-Off Products

Carbon monoxide, methane, and gas chromatographic analyses were performed by techniques reported earlier 1,2 . All atmospheres in the test chamber were sampled for analysis at the temperature of the test, i.e., 25°C or 68° C.

The general analyses of the gas-off products by gas chromatography were performed on an F&M Model 810 Research Gas Chromatograph equipped with dual flame ionization detectors. A general purpose column, 20-ft x 0.25-in. ss., 20% Triton X-305 on 60/80 mesh Gas Chrom Z was used for most samples. Gas-off products from four samples (DAC 006, DAC 017, DAC 018, and DAC 020), tested in the first quarter of the program, were analyzed by means of a double column, 20-ft x 0.25-in. ss., 5% Carbowax 20M on 60/80 mesh Gas-Pack F with a pre-column of 12-ft x 1/8-in. ss., 7% neopentylglycolsuccinate on 60/80 mesh Gas Pack F, used

earlier². The advantage of using the Triton X-305 column is better separation of early eluting components.

Quantitative gas chromatography data were obtained by comparing the peak heights with those of a standard mixture. Gas chromatographic instrument conditions are presented in Appendix III, Table XLV.

Identifications of gas chromatographic components were made by mass spectrometric analysis of the gas chromatographic effluent. In most cases component identification was accomplished by the direct, tandem coupling of a fast scan mass spectrometer, CEC 21-104, to the gas chromatograph. By splitting the effluent, a portion was directed to the flame ionization detector and a second portion was introduced directly into the mass spectrometer. With some samples, a concentration step requiring the cryogenic trapping of the major portion of the total 9-liter volume was necessary. This condensate was subsequently separated into its components and characterized by the coupled gas chromatograph-mass spectrometer system.

c. Mass Spectrometric Analysis of Gas-Off Products

Two types of mass spectrometric analyses were performed for each sample. A composite analysis¹ of the atmosphere of each 9-liter bottle was made on an aliquot (125 cc) of the atmosphere with a Consolidated Electrodynamics Corporation Model 21-103C Mass Spectrometer. As indicated in Section II-A-3-b, a fast scan Consolidated Electrodynamics Corporation Model 21-104 Mass Spectrometer was used in a direct couple with a gas chromatograph to identify the components eluting from the chromatograph. Both approaches are necessary to insure complete characterization of the chamber atmospheres.

Identifications of individual components were made by mass spectrometry and were supported by infrared absorption and by gas chromatographic data as needed. Most of the mass spectra obtained were compared to API (American Petroleum Institute) reference spectra. In cases where the required mass spectrum does not appear in the API collection, comparison was made with spectra from our laboratory files or from the literature.

B. RESULTS AND DISCUSSION

Table II lists the types of compounds detected in the chamber atmospheres. These data represent compounds exclusive of $\rm H_2O$, $\rm CO_2$, $\rm O_2$, and $\rm N_2$.

Various Cyclic and Linear Methylsiloxane Polymers

A STATE OF THE STA

Materials that showed no products (exclusive of H₂O, CO₂, O_2 , and N_2) are listed in Table III.

Materials showing weight loss in excess of 1% and for which no analytical data were obtained are listed in Table IV. Although these materials were conditionally screened and eliminated from further testing based on TGA measurements, all candidate materials in this program were processed in storage tests for 72 hours, 30 days, and 60 days, and their gas-off products were analyzed with gas chromatography and mass spectrometry to confirm the results of the TGA measurements. In most cases, where the weight loss exceeded 1%, gas chromatographic and mass spectrometric data were obtained, only to establish the magnitude of the total off-gases. No specific identifications or measurement of quantities of individual components have been made. Others were analyzed completely for comparison purposes with the TGA data.

Analytical data are presented in Appendix I, Table V, Figures 4 to 56 (Thermogravimetric Weight Loss Data and TGA Curves); Appendix II, Tables VI to LXIV (Analytical Results for Gas-Off Experiments); and Appendix III, Figures 57 to 95 (Gas Chromatograms for Gas-Off Experiments).

All values appearing in the tables of Appendices I and II are calculated on the basis of the dried or cured samples (this is important in the case of paints and coatings where the weight of the material is substantially reduced by drying).

Some gas-off products are identified by compound type only, e.g., alkylbenzene(s), C4 alkylbenzene(s), or C4 hydrocarbon. In these cases several homologues or isomers may be present; however, they have not been identified individually.

Some of the gas-off products from silicone base materials were also calculated collectively. These were the volatile linear and cyclic siloxane polymers (having dimethyl siloxy groups as monomer units), which had been observed in previous gas-off studies^{1,2}. Although separate peaks are noted in the gas chromatograms (Appendix III), these volatile silicones are listed collectively in the tables of gas-off data (Appendix II) as silicone oil.

Although no distinct correlation of composition and the shape of the TGA curve can be derived from the limited data, some similarities in TGA curves are noted, e.g., two materials containing polyamide [DAC 007, Shonka A-150 Polyolefin/Polyamide (Figure 9) and AF 054, Epoxy-Polyamide, V-9 Silver Spon 815 (Figure 23)]. Also, certain similarities in the total weight loss data are observed for materials of a particular type, e.g.,

AF 063 (Silicone Rubber EMS 323), AF 065 (Silicone Rubber EMS 342), and AF 066 (Silicone Rubber EMS 345) lost 0.25%, 0.26%, and 0.26% of their weight, respectively. However, the significance of this observation is not clear since other, non-silicone materials, also exhibit weight loss of similar proportions.

The need for gas chromatographic and mass spectrometric confirmatory evidence in the screening of the candidate materials by TGA measurement results from the inability to measure quantitatively the amount of water evolved during the TGA measurement. The reliability of the two gas chromatographic methods for water, i.e., (a) conversion to acetylene and subsequent acetylene analysis, and (b) direct analysis for water, was established through the use of known water standards. However, difficulty was encountered when attempting to distinguish the water evolved from the sample, from that present in the pre-dried, pre-purified nitrogen used as the atmosphere and from that adsorbed on the inner surface of the TGA apparatus.

Although the amount of water present in the apparatus is very small, apparently there are sufficient quantities adsorbed on the glass at 23 to 68°C to yield a relatively large amount into the gas phase during a 24-hour test. Although not conclusive, an apparent adsorption-desorption equilibrium is established with the sample, metal and glass surfaces of the apparatus, and the gas phase, such that a relatively constant amount of water (20-28 mg) is isolated during a 24-hour test. Experiments performed without sample to establish the background level of water yielded similar quantities of water. To eliminate this problem, the apparatus is being modified to provide a direct measure of water desorbed from the sample by locating a hygrometer probe at the sample site.

A comparison of weight loss data (23 to 68°C) with the quantitative analyses of volatiles from storage tests at 68°C should be made with care. Several opposing effects should be noted. A large number of materials continue to desorb considerable quantities of volatiles after 24 hours. Thus, more gas-off products should be present in the atmosphere during 72-hour tests than gas-off products detected as weight loss during 24-hour TGA measurements. However, adsorption of volatiles on chamber surfaces results in an opposing effect. Considerable quantities of polar and relatively non-volatile gas-off products are retained on the chamber surfaces in the storage tests even at 68°C. Oily films were deposited on chamber walls in many of the tests. This effect was particularly noticeable when testing silicones, in that, relatively low molecular weight silicone oil condensed on

· (1) (2) \$10 8.00 (2)

the chamber surfaces. Similarly, considerable amounts of butoxy-ethylacetate (identified by infrared spectra) were collected on the surfaces of test chambers for AF 522.

Material No. DAC 014, Hathone HA 7236, a polymeric foam, showed an unusual behavior during the TGA measurements. Solid material in the form of a fine dust was lost from the crucible. This was perhaps due to the rupture of gas-filled bubbles resulting from the decreased pressure (5 psia). Collection of the dust for weighing was difficult due to the static charge associated with this type of material, but it was estimated to be approximately 2-3 mgs for a 2-g specimen. The formation of this dust could perhaps, in itself, be considered a significant atmospheric contaminant.

THE PARTY OF THE

SECTION III

BIO-ENVIRONMENTAL AND SPECIAL ANALYSES

A special study was performed to determine the gas-off products of Hetron Polyester Resin. This material is not a candidate space cabin material, but it is of interest to the Government as a construction material for terrestrial use. Ten grams of the material was stored in a 9-liter gas-off chamber for 30 days in an air atmosphere at a pressure of 1 atmosphere at 25°C. The most abundant product observed in the off-gases was methylethyl-ketone. This compound undoubtedly arises from methylethylketone peroxide used in the formulation of the polymer. However, due to lack of data on the stability of MEK peroxide, it has not been established whether the peroxide decomposes during storage or during analysis. Table XLVI lists the gas-off products from this material.

Special analyses Nos. 2 and 3 were performed on air specimens collected on 28 March 1967 from an Air Force test chamber and from the room air immediately outside the chamber. Data from these analyses are shown in Table XLVII.

Special analyses Nos. 4, 5, 6 and 7 were performed on bioenvironmental specimens contained in four 50-liter cylinders which were received from the Air Force on 25 August 1967. The results, given in Table XLVIII, are exclusive of water and carbon dioxide. It will be noted that low molecular weight chlorinated fluorocarbons are present in cylinder #1 (sample No. 4). These appear to be similar to the volatiles which have been observed to arise from certain fluorocarbon lubricants.

行的 (大學問題) The

SECTION IV

CONCLUSIONS AND RECOMMENDATIONS

Considerable differences in levels of volatiles as determined from weight-loss measurements (TGA) and from storage tests and analyses of atmosphere of the storage chambers are observed. A major contributing factor is the adsorption of volatiles on the chamber walls.

The application of thermogravimetric measurements for screening candidate materials has proven useful, but a more direct measurement of water at the sample site must be made to provide more reliable data. We recommend the use of a hygrometer probe at the sample site. Such a device is being incorporated in a modification of the TGA system used in this test program. Until a reliable direct water analysis can be performed, we recommend continued 72 hours storage tests at 68°C and attendant atmosphere analyses to confirm the level of volatile products desorbed from the candidate materials.

THERMOGRAVIMETRIC PATTERNS OF CANDIDATE SPACE CABIN MATERIALS

美国的美国教育

The thermogravimetric analysis (TGA) patterns shown in this appendix were obtained on a Cahn RH Electrobalance. Comparison of the weight loss patterns should be made with care since varying amounts of sample were used to obtain the TGA patterns. The quantity of material used for each TGA measurement is shown on the reproduced pattern.

TGA curves appear in order of their Air Force serial numbers. Names of materials are those submitted by the Air Force.

APPENDIX II

ANALYTICAL RESULTS
FOR
GAS-OFF EXPERIMENTS

Compounds found as gas-off products from candidate space cabin materials are listed in the following tables. Values for the gas-off product levels are given as: milligrams per 10 grams (mg/10 gms) of the cured candidate material. In some cases, either more or less than 10 g of material was used, but each yield of gas-off products was normalized to that of a 10-g sample.

The order of the tables in this appendix is by Air Force serial number. Names of materials are those submitted by the Air Force.

APPENDIX III

REPRESENTATIVE GAS CHROMATOGRAMS
FOR
GAS-OFF EXPERIMENTS

Sales and Selection of the Military of the Selection of t

The gas chromatograms shown in this appendix were obtained on an F&M Scientific Corporation Model 810 Research Gas Chromatograph. Instrument conditions and column specifications are listed in Table XLV. Since retention times tended to shift somewhat due to column aging, a standard mixture was used as a day-to-day reference.

The gas chromatograms are representative of a particular candidate material. Comparison of peak intensities in chromatograms for different candidate materials should be made with care, since sensitivity factors and quantities of atmosphere taken for analysis vary.

Chromatograms appear in order of their Air Force serial numbers. Names of materials are those submitted by the Air Force.

Table XLV

GAS CHROMATOGRAPHIC INSTRUMENT CONDITIONS

All samples were analyzed using a flame ionization detector and a F&M Model 810 Research Gas Chromatograph.

Instrument Conditions

I. Column: 12-ft x 1/8-in O.D. Stainless Steel, 7% neopentylglycolsuccinate on 60/80 mesh Gas-Pack F + 20-ft x
1/4-in. O.D., 5% Carbowax 20M on 60/80 mesh GasPack F.

Column Temperature: programmed 50°-185°C € 8°C/min.

Detector Temperature: 275°C

Injection Port Temperature: 250°C

Flow Split: 1:9

Flow Rate: 60 ml/min.

Range: 10

Attenuation: X8, or as noted

Sample Size: 25 cc of gas

II. Column: 20-ft x 1/4-in O.D. Stainless Steel, 20% Triton X-305 on 60/80 mesh Gas Chrom Z.

Column Temperature: programmed 50°-170°C @ 8°C/min.

Detector Temperature: 300°C

Injection Port Temperature: 250°C

Flow Split: none

Flow Rate: 60 ml/min.

Range: 10

Attenuation: X8, or as noted

Sample Size: 50 cc of gas
