## Daca Analysis

E. M. Gaposchkin devoted much of his time during this quarter toward improving the Geos 1 data results that were presented in his paper "Numerical Results from Geos 1." The paper derives station coordinates in the SAO system for several stations in the SECOR, GRARR, and TRANET doppler networks and for miscellaneous optical stations. Retitled "Dynamical Determination of Station Locations Using Geos 1 Data, " the paper is included as an appendix to this report.

Also, a good portion of the computation effort this quarter was directed toward an analysis of data to redetermine the zonal harmonics from observation files spanning very long periods of time. This, redetermination will refine existing values, paying particular attention to reference systems and homogeneity of data. The project should be completed in late May.

## Data Reduction

At a meeting in March, Gaposchkin, Dr. C. A. Lundquist, and Dr. K. Lambeck decided that it would be analytically advantageous for the dynamical geodesy program to fill in gaps in satellite orbital inclinations where possible. For this reason, the low-inclination ( $28^{\circ}$ ) Satellite 196013 A was scheduled for reduction analysis, to be followed immediately by a high-inclination $\left(144^{\circ}\right)$ file of observations of Satellite 1965 78A. The end-of-the-quarter status of normal and select observation files used for geodetic studies is given in Tables 1 and 2. We decided to postpone reduction of the backup 1965 78A file (Normal File No. 30) and the 196563 A file (Select File No. 30)
in favor of a number of simultaneous observations. The simultaneous observations chosen will extend the SAO geometric network to the new SAO stations in Argentina, Brazil, Ethiopia, and Groece (see Table 3). Since a geometric station-position solution is, of course, an important adjunct to any standardearth determination, we will devote some 3 to 4 months of photoreduction effort to this solution.

## International Participation

In February, SAO scientists met with scientists from the French National Space Agency (CNES) and the Paris Observatory, during which time we informally agreed upon a program of cooperative observing of the laser reflecting satellites (including Geos 2 ) similar to last year's successful activity. There was also an exchange of observational data resulting from the previous activity. SAO now has on file more than 78, 000 French lacer range observations, as shown in Table 4. The French are continuing to process their optical and doppler data.

The French analysis emphasizes the regional geometric aspect of satellite geodesy, while SAO's program stresses the dynamic technique. Hence, it was agreed that the French would coordinate simultaneous laser-optical observations in the European area, while SAO would coordinate intensive globai observing periods for dynamic geodesy. Visibility patterns for the six satellites were studied to determine an optimum observing schedule for this year (see Table 5).

Observatories in Helsinki, Finland; Riga, Latvia; and Uzhgorod, USSR, have reported successful Geos 2 flash observations.

DYNAMICAL DETERMINATION OF STATION LOCATIONS USING GEOS I DATA
E. M. Gaposchkin

April 1968

# DYNAMICAL DETERMINATION OF STATION LOCATIONS USING GEOS ! DATA 

E. M. Gaposchkin

## 1. INTRODUCTION

The Smithsonian Astrophysical Observatory (SAO) has for some years been actively engaged in a geodesy program. This field of study is in the process of expansion through the acquisition of new sources of data, new methors of data analysis, and the combination of satellite geodesy with classical techniques. The general background, basic concepts, and broad context of this prog.am will be discussed in separate papers by Lundquist and Rolff.

Our most recent significant achievement was the publication in 1966 of the Smithsonian Institution Standard Earth (Lundquist and Veis, 1966), which was based entirely on Baker-Nunn camera observations. Before this work was accomplished, we had already recognized that a wider distribution of data and a greater variety of data types would improve geodetic results.

We are encouraged in the expansion of our program by the investigations currently pursued by the Applied Physics Laboratory of Johns Hopkins University (APL) and by the Naval Weapons Laboratory (NWL) with the use of electronic TRANET doppler data. It is reassuring that the geodetic results obtained by SAO, APL, and NWL are in reasonably good agreement. The combination of the data from these sources is a logical advance in geodetic studies. Moreover, additional sources of data are becoming available. Smaller observatories and geodetic institutes can participate in global geodetic investigations with an illuminated satellite. Newer electronic systems such as the Goddard Range and Range Rate (GRARR) and the SECOR systems are beginning to acquire data in fairly large amounts, and the development of laser tracking provides greater accuracy.

[^2]The first step in combining different kinds of data to solve the geodetic problem involves selection of additional data types, establishment of suitable variances, reduction to a uniform tis. and spatial reference system, and, as pait of the last item, adoption of aninitial set of station locations. A geodetic satellite such as Geos 1 is ideal for these tasks. Each of the cooperating agencies has acquired data from this satellite, and its orbital characteristics are such that we can be reasonably confident in using a dynamical theory.

## 2. SCOPE AND GOALS OF THIS STUDY

First, and most important, we have used data from a variety of tracking systems (optical directions, range, and range rate) to determine station locations in a geocentric Cartesian coordinate system. Second, having performed this adjustment, we have obtained some measure of the validity, accuracy, and potential usefulness of these data-acquisition systems for future work.

Our approach to the problem is the so-called dynamical method, which is discussed in detail in the Smithsonian Institution Standard Earth. Some use will be made of simultaneous optical observations to ascertain the validity of the positions of the optical stations determined in our reference system.

I assert that the results given here are only an indication of the accuracy of the system, and in the final analysis, a dynamical theory cannot be used to calibrate an observing system with an accuracy greater than 100 m . Such a calibration can be performed only by intercomparison.

## 3. REFERENCE SYSTEMS AND ORBITAL ACCURACIES

The 1966 Smithsonian Institution Standard Earth forms the basis for this analysis. The coordinate systems are briefly as follows. The inertial reference frame is referred to the equinox of 1950.0 and the equator of date.

The terrestrial reference frame is referred to the mean pole of 1400.0 to 1905. 0 and the longitude of the mean observatory at Greenwith. The coordinates of the SAO Baker-Nunn cameras expressed in this terrestrial system are the C6 coordinates of the Standard Earth. The relation between these two frames of reference is given by the measured values of the time UTI and the position of the pole.

The usefulness of the dynamical method hinges exclusively upon the accuracy of the orbital ephemeris. This, in turn, depends on the accuracy of the orbit theory itself, which includes uncertainties in the earth gravityfield model adopted, and on the accuracy with which the orbital elements of the satellite can be determined. Unfortunately, Geos 1 was in an orbit that is resonant with some of the 12 th-order tesseral harmonics. Therefore, before any attempt can be made to use the dynamical method, these harmonics must be determined quite accurately.

The important harmonics with which Geos 1 is resonant are $\ell, m=12,12$; 13,12; 14, 12; and 15,12. One satellite 18 not adequate for the determination of the eight re-merical parameters. Fortunately, we have observations of another satellite, $1960\llcorner 2$, resonant with the same harmonics and of essentially different orbital characteristics. The required harmonics can be determined by the combined use of these two satellites.

Table 1 gives the orbital characteristics of Geos 1 and $1960 \downarrow 2$, with other relevant information. The first step, then, is to determine the resonant gravity-field harmonics from optical observations of these two satellites. The harmonic coefficients determined in this way are shown, with additional geodetic information, in Table 2.

The question of the accuracy of the reference orbits can be answered, in part, by the range observations acquired by the SAO laser tracking systern collocated with the SAO Baker-Nunn camera at Organ Pass, New Mexico (station 9001). The collocation eliminates any problem of possible timingsystem differences or errors in te station coordinates. If we use the
reference orbits computed without the laser observations and compare the computed ranges with the laser observations, we get a measure of the accuracy in an absolute sense of the orbit theory. The mean value of 20 m agress quite well with previous estimates of the orbital accuracy and must be taken to be the accuracy we can expect.

| 13 |  | 490 meters | 360 meters |
| 14 |  | 90 meters | 26 meters |
|  |  | 310 meters | 630 neters |
| Period of perturbation: |  | 7.1 days | 14.5 days |

Table 2. Geodetic constants

[^3]The mean elements of these reference orbits are plotted in Figure 1. We note that the semimajor axis has a consistent variation of not more than 10 m . The eccentricity and inclination show the long-period effect of the earth's oblateness; this effect has a period of 550 days. Including the laser observations in the orbit determination does not change the values of the elements to any significant extent, and the mean value of the range residuals computed with respect to these orbits is 10 m .

As stated in Lundquist and Veis (1966), the internal consistency of the fundamental Baker-Nunn coordinates is 15 m . The orbital ephemeris is computed for 1 -month arcs and has an accuracy of 20 m . Therefore, we cannot hope to determine the station positions to an accuracy better than 15 to 20 m .

Figure 1. Mean inclination, eccentricity, and semimajor axis of Geos 1 for November 1965 to October 1966.

## 4. DETERMINATION OF THE LOCATIONS OF NNE MISCELLANEOUS OPTICAL SITES

The flashing light of Geos 1 was observed by several observatories. The cuordination of the flashes removed the problems of mixed time systems. The observation of a flash sequence provided a set of points. We reduced each flash sequence to a synthetic observation for use in the dynamical determination of the station coordinates. These observations seemed to have an accuracy of nearly 1 arcsec.

The essential results are given in Table 3. The initial coordinates, the corrections, and the resulting coordinates are shown in the columns labeled $X, Y$, and $Z$. The numbers of synthetic observations are also given. For all stations except 9113, a direction to this previously unk nown station from an SAO station had been determined by the use of simultaneous observations. In general, these directions are determined fror, other satellites as well. If the distance between the stations is known, this direction would suffice to determine the station coordinates uniquely. If we adopt the dynamically determined position to compute the distance, we can compute the location. The equivalent corrections from this method are also given in Table 3. This calculation is merely a consistency check.

In general, the agreement is good when there are sufficient observations. The coordinates for Rosamund seem well determined. The three stations at Cold Lake, Harvestua, and Johnston Island were determined in the Standard Earth. In each case the data were feu and were acquired from geodetically less useful satellites. Since Geos 1 is essentially a better satellite, more orbital arcs are used here, and the agreement with the directions is good, the coordinates determined from Gens 1 for Cold Lake and Harvestua are preferable to the earlier results. Nevertheless, the number of observations is marginal, and these coordinates can be considered only provisional. Since

for Johnston laland the agreement between the direction and the dynamical determination is poor, and since there are sof observations, this determination must be considered unreliable. The remaining stations are all new. Haute Provence and Zimmerwald are clearly well determined. Because of the small number of observations at Agasiz and Malvern, the determination would have to be provisional, but the good agreement between the direction and the dynamical determination is very encouraging. Riga is a first attempt.

## 5. DETERMINATION OF THE SECOR RANGE STATIONS

The Goddard Data Bank provided us with more than 20,000 observations from four stations. These data were obtained from as many as l7 passes from each station. In our opinion, much of this large volume of data was redundant. We therefore removed 9 of every 10 observed points, rather than fitting polynomials to the 10 points to compute a synthetic observation, because the data from each pass were extremely coherent. The noise level from the mean was 5 m or less. Nothing would have been gained by the use of synthetic points.

SECOR data have a range ambiguity of 256 m . This is because the equipment is so constructed that the range is determine from the properties of an electromagnetic wave with a $256-m$ wavelength. The analysis must provide the range to within that accuracy. Therefore, in the determination of station locations, we used the residuals modulo 256 m . Hence, we never computed a residual greater than 128 m . We rejected residuals greater than 100 m .

Table 4 summarizes the data available. It details the standarderrors $(\sigma)$ and the corrections to the station locations computed. Because of the small number of passes available and the standarderror relative to the rejection criterion, we consider this determination unacceptable. In Table 4 the corrections are resolved into the height component because this sometimes provides an insight into possible problems with an ionospheric or elevation correction. This is not the case here. Table 5 gives the initial coordinates used for these stations.

Table 4. Dynamical determination of atation coordinates (SECOR)

|  | Station |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  | 5001 Herndon Virginia | $\begin{aligned} & 5333 \\ & \text { Creenville } \\ & \text { Miociooippi } \end{aligned}$ | $\begin{aligned} & \text { Ft. Stewart } \\ & \text { Georgia } \end{aligned}$ | $\begin{gathered} 5861 \\ \text { Homestead } \\ \text { Florida } \end{gathered}$ |
| January '66 panaca | 4 | 5 | 5 | 4 |
| February '66 pasace | 1 | 1 | 1 | 1 |
| March '66 passes | 6 | 5 | 3 | 5 |
| April '66 passea | 6 | 6 | - | 5 |
| Total passes | 17 | 16 | 9 | 15 |
| Number of observations | 742 | 641 | 219 | 550 |
| - (m) | 48 | 53 | 54 | 54 |
| Correctione (m) |  |  |  |  |
| $d x$ | 10 | -9 | 8 | -10 |
| dy | 5 | 4 | . 31 | 20 |
| dz | 29 | 12 | -48 | 27 |
| dh | 18 | 3 | 11 | - 7 |
| Range ambiguity of 256 m removeo |  |  |  |  |
| Maximum residual accepted $= \pm 100 \mathrm{~m}$ |  |  |  |  |

The small number of passes would not allow a very good determination of the station locations. However, the size of the standard error comes from the data set itself. Either difficulties in converting the time systems or systematic errors in the data seem the most likely reasons for the large standard error.

## 6. DETERMINATION OF THE GRARR STATIONS

The GRARR system provides both distance and velocity measurements. Geos 1 was observed from three stations during the interval of our precise orbits. By far the largest amount of data came from the station at Rosman, North Carolina.

It was found that careful data selection was necessary. We obtained the raw data directly from Goddard and developed our own reduction methods and rejection criteria. During that phase of the analysis we were in close contact with the Goddard Intercomparison Effort, and we were fortunate to be able to incorporate their findings into our analysis. We found polynomial fitting to short intervals (e.g., 20 sec ) valuable for two reasons: First, the smoothed or synthetic points provided significantly better results for stationcoordinate decermination than did the raw data points used "en masse." Secord, the standard error of the curve fit proved to be an excellent rejection criter: For the range rate data we used virtually all the data available. For the range data, a rejection criterion of 8 m in the curve fit satisfactorily discriminated good from bad passes. The $8-\mathrm{m}$ criterion should not be interpreted as the accuracy of the data; it is only a measure of the internal consistency of the data for a short interval.

Table 6 detalls the results of the determination of three stations. Five points per pase were used. Clearly, the combination olution depend on the adoped uncertainties of the two kinds of data, and these were taken at 30 m for range and $15 \mathrm{~cm}_{\mathrm{sec}}{ }^{-1}$ for range rate. In addition, the relative number of data points is important. We rejected residuals at 100 m for range and $45 \mathrm{~cm} \mathrm{sec}{ }^{-1}$ for range rate. Since the correction for station 4714 was larger that the rejection criterion, we performed a econd iteration to verify convergence.

The results for station 4713 are quite reasonable; the data set was good. The initial coordinates were given in the North Americandatum. In addition, the effective correction of 16 m in height agrees with the determination by Brown (1967) is om shortarc studies. The Madagascar and Australian coordinates must be considered preliminary at this stage. The small amount of data, the lack of a comparison, the high rejection rate of the data, and the lack of timing records all support this conclusion.

## 7. DETERMINATION OF THE TRANET DOPPLER STATIONS

The TRANET network provided data from 10 stations, generally 30 points per pass. The data were availabie through the entire period of precine orbits. The ionospheric correction had, of course, been removed. In addition, a preliminary frequency correction had been applied. These dopriler data were treated in the same way as the Goddard range rate data.

Table 7 gives the corrections computed for the 10 sites. The initial coordinates were heterogeneous. As designated in Table 7, six stations were initially taken from an APL solution (H. Black, 1968, private communication); the remaining were taken from the Goddard directory. However, some comparisons are possible. Any solution fnr station coordinates computed solely with electronic data is indeterminate by one longitude. If the longitude of one station is fixed, a unique solution is possible. Therefore, for solutions to be compared, this rotation must be removed.

| 7745 <br> Stoneville, Mississippi | 0.89 | 4279 | -66 | -35 | -27 |

Assumed accuracy $=15 \mathrm{~cm} \mathrm{sec}{ }^{-1}$; rejection criterion $=45 \mathrm{crr}_{\mathrm{sec}}{ }^{-1}$.
*Initial coordinates APL 3.5 solution.

With several points given in swo coordinate systems that differ by a rotation, this rotation can be determined. If we introduce the infinitesimal rotation (Goldstein, 1950, p. 124) $\mathcal{R}\left(d \Omega_{1}, d \Omega_{2}, d \Omega_{3}\right)$ such that

$$
\Omega\left(d \Omega_{1}, d \Omega_{2}, d \Omega_{3}\right)=\left[\begin{array}{ccc}
1 & d \Omega_{3} & -d \Omega_{2} \\
-d \Omega_{3} & 1 & d \Omega_{1} \\
d \Omega_{2} & -d \Omega_{1} & 1
\end{array}\right]
$$

we want to find $d \Omega_{i}$ such that

$$
\bar{x}_{j}^{S A O}=\mathcal{R}_{\left(\mathrm{d} \Omega_{i}\right)} \bar{x}_{j}^{A P L}
$$

We have three candidates for such a computation and comparison: the APL 3. 5 ccordinates, a set of coordinates given by Anderle and Smith (1967), and a set attributed to Guier and Yionoulis (Anderle and Smith, 1967). These three sets of coordinates will be designated as $X_{j}^{A P L}, X_{j}^{A}$, and $X_{j}^{G Y}$, respectively. In each case, the subset of stations is different. During the comparison, the determinations of $X_{7017}^{S A O}$ and $X_{7019}^{S A O}$ showed large disagreement and were therefore not included in the determination of the relative positions of the reference systems. Table 8 gives the relative rotations of the reference systems in seconds of arc and the standard error of the determination in meters. The rotation in terms of meters at the surface of the earth is also included.

The physical significance of the $d \Omega_{3}$ is a rotation in longitude and corresponds to the difference in the adopted longitude of the TRANET solutions and the longitude of the mean observatory; $d \Omega_{1}$ and $d \Omega_{2}$ would correspond to the differences in the adopted pole of the difference solutions. While SAO used observed values of the polar motion in its analysis, none of these data were used for the TRANET solutions (Black, 1968, private communication); hence, the resulting pole is defined by a mean of the data arcs used. The computed values are consistent in sign and magnitude with this interpretation.

The differences in the values of GM used in the solutions are small, as evidenced by the values adopted (Lundquist and Veis, 1966; Black, 1968, private communication):

$$
\begin{aligned}
& \bar{X}_{j}^{A} \quad G M=3.986010 \times 10^{8} \mathrm{Mm}^{3} \mathrm{sec}^{-2} \\
& \bar{X}_{j}^{S A O} G M=3.986013 \times 10^{8} \mathrm{Mm}^{3} \mathrm{sec}^{-2} \\
& \bar{X}_{j}^{G Y} G M=3.986015 \times 10^{8} \mathrm{Mm}^{3} \mathrm{sec}^{-2} .
\end{aligned}
$$

Table 8. Relation between the various reference systems: SAO C6 coordinates (SAO); APL 3.5 coordinates (APL); Anderle coordinates (A); Guier and Yionoulis coordinates (GY).

|  | $\mathrm{d} \Omega_{1}$ <br> $(\mathrm{arcsec})$ | $\mathrm{d} \Omega_{2}$ <br> $(\mathrm{arcsec})$ | $\mathrm{d} \Omega_{3}$ <br> $(\mathrm{arcsec})$ | $\mathrm{a}_{\mathrm{e}} \mathrm{d} \Omega_{1}$ <br> $(\mathrm{~m})$ | $a_{e} \mathrm{~d} \Omega_{2}$ <br> $(\mathrm{~m})$ | $a_{e} d \Omega_{3}$ <br> $(\mathrm{~m})$ | $\sigma$ <br> $(\mathrm{m})$ |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| SAO-APL | -0.02 | 0.42 | 1.24 | 0 | 13 | 41 | 41 |
| SAO-GY | -0.93 | 0.35 | 2.11 | -28 | 10 | 65 | 35 |
| SAO-A | -0.85 | 0.36 | 0.91 | -26 | 11 | 28 | 18 |
| A-GY | -0.08 | -0.03 | 0.94 | -2 | -1 | 29 | 13 |

The standard errors of 18 m for the Anderle solution relative to the SAO solution and of 35 m for the Guier and Yionoulis solution relative to the SAO solution are quite satisfactory in view of the $13-\mathrm{m}$ agreement between the A and the GY (Table 8). Considering that both the TRANET solutions also used other satellites and involved a further improvement of the frequency and tropospheric correction, their reliability is much enhanced. This is especially true for station 7019 , which is at $-77^{\circ}$ latitude. Since Geos 1 is of $59^{\circ}$ inclination, all the data used in our analysis were low passes to the north, which resulted in very poor geometry. The poor results from station 7017 cannot be attributed to its latitude. Table 9 provides the final coordinates determined from GEOS 1.

Table 9. Final coordinates of the TRANET stations

| Station | $\mathbf{x}_{j}^{\mathbf{S A O}}$ |  |  | $\mathrm{X}_{\mathrm{jAO}}$ |  | $X_{j}^{A}$ |

## 8. SUMMARY AND CONCLUSIONS

The geodetic satellite Geos 1 has been immensely successful in the determination of the locations of many new stations in the SAO C6 system. In some cases these coordinates are preliminary, in the sense that the determination is thought to he significantly worse than the $20-\mathrm{m}$ accuracy that could be desired. Where stations had previously been determined by earlier and more comprehensive analysis, these results can be viewed as
a confirmation of our technique, and an adjustment or average may provide somewhat more realistic results. The values determined for the relation between the SAO and the TRANET systems are considerably more reliable than any of the individual determinations. In any case, the station coordinates determined here are suitable for an initial set to be used in future large-scale solutions. It is quite clear that it is desirable and feasible to combine the SAO Baker-Nunn observations, other optical observations of good quality, and GRARR, TRANET, and laser observations in a comprehensive global soiution for station coordinates and the gravity field with the use of a wide variety of satellites.
