FOR EWORD

This Technical Report describes one of three computer programs which were developed as tools for generating parametric weight and design data for nose fairings suitable for Saturn-class payloads. The work was performed by Lockheed Missiles & Space Company, Huntsville Research & Engineering Center, with support from the LMSC/Palo Alto Research Laboratories, for the National Aeronautics and Space Administration/Marshall Space Flight Center under Contract NAS8-15485, from July through November 1965.

The three computer programs developed under this contract are described in the following three reports.

1. Automated Nose Fairing Design -- Ring and Skin Construction, LMSC Technical Report LMSC/HREC A712552, November 1965.
2. Automated Nose Fairing Design -- Ring, Skin and Stringer Construction, LMSC Technical Report LMSC/HREC A712572 November 1965.
3. Automated Nose Fairing Design -- Honeycomb Sandwich Construction, LMSC Technical Report LMSC/HREC A712573 November 1965.

Many of the subroutines and the methods of specifying external geometry and aerodynamics loads are common to all three programs.

This report (which describes the computer program for ring and skin construction) supersedes LMSC Technical Report LMSC/HREC A711099 which describes an earlier version of the same program. Major contributors to the development of this computer program were A. B. Burns ~~ET AL~~ RCV the Palo Alto Research Laboratories and E. S. Hendrix and I. M. Landis of Huntsville Research & Engineering Center. Appendix K of this report was written by A. B. Burns, and the remainder was written by I. M. Landis.

SUMMARY

The computer program described in this report determines the optimum design for ring-stiffened sheet metal nose fairings with an external geometry consisting of up to ten intersecting conical frustums (or cylinders) capped with a spherical nose cap. The combined effects of bending moments, axial loading due to drag, and lateral pressure are considered in performing the design. Only standard gauge materials are used in the design of the shell and rings. Because of the difficulty of applying the more powerful mathematical techniques to optimizing such a design, the designer is limited to time-consuming "cut-and-try" procedures in his search for the minimum weight design. These procedures have been methodically arranged and mechanized in the Fortran IV computer program described in this report.

The main part of the report is devoted to description of the logic followed in designing a fairing, description of the computer program, and instructions on operation of the program. The program listing and details of the methods of analysis used in design of fairing appear in the Appendixes.

INTRODUCTION

The computer program described in this report determines the optimum structural design of ring stiffened, sheet metal nose fairings. When external geometry, aerodynamic loading, and a practical set of design constraints are given, the computer program selects the combination of sheet metal thickness, ring cross-section and ring spacing which results in the minimum fairing weight. (Sheet metal will be referred to as "skin" throughout the remainder of the report.) Only standard sheet metal gauges are considered for design of the skin and rings. The external geometry can consist of up to ten intersecting conical frustums (or cylinders) capped with a spherical nose cap. Figure 1 illustrates both the external geometry and the type of construction.

A condensed flow chart illustrating the major logical steps performed in the program is shown in Figure 2. Design begins at the base of the fairing and moves toward the nose cap. Each bay is designed to withstand loads imposed by the interaction of bending moments, axial loading and lateral pressure. The combination of skin thickness, bay length and ring cross-section which results in the minimum weight-to-volume ratio for the bay is considered to be the optimum design for the bay. An additional constraint placed on the design of the top frustum and nose cap is the maximum temperature to be reached by the skin due to aerodynamic heating. The computer program does this by computing the minimum skin thickness to be used in each of these areas.

The computer program consists of the main program and fourteen subroutines. The logical steps to be followed in designing the fairing and minor design calculations are performed in the main program. Specialized functions, such as computation of aerodynamic loads, are performed in the subroutines. This arrangement permits the methods of analysis used in designing the fairing to be easily modified.

TECHNICAL DISCUSSION

1.0 THE MAIN PROGRAM

1.1 Terminology and Geometric Parameters

Following are definitions of terms used in this technical discussion. The terms are also illustrated in Figure 1.

base - the bottom end of the bay, frustum or fairing

bay - the section of skin between two rings plus the ring at the upper end of this section

frustum - the section of fairing consisting of all bays having the same half angle

nose cap - the spherical segment which closes the top of the fairing.

The external geometry of the fairing is specified by the base diameter of the fairing (DBAS), by the half-angle of each frustum (THTA (NF)), and either the ratio of the top diameter of each frustum to the base diameter of the fairing (DOVDB (NF)), or (mandatory when the frustum is a cylinder) the length of the frustum (ALF (NF)). Frustums are numbered by index NF starting at the base of the fairing. Frustum geometry is completely described by the same parameters used to describe fairing geometry. Bay geometry is described by the base diameter of the bay (DSUBB), the half angle of the bay (THETA), and the length of the bay measured along the axis of symmetry (ALB). Bays within a frustum are numbered by index I starting at the base of the frustum. The outside diameter of a ring associated with a bay is equal to the top diameter of the bay. All dimensions of the ring cross-section are expressed in terms of the material thickness used to form the ring (see Figure 3). This thickness will be one of the standard gauges stored in the program.

1.2 Design Logic

The major logical steps followed in designing a nose fairing are shown in the condensed flow chart in Figure 2. In Appendix A, more detailed information is provided by a program listing which includes detailed comments describing in words the operations being performed. Definitions of the more

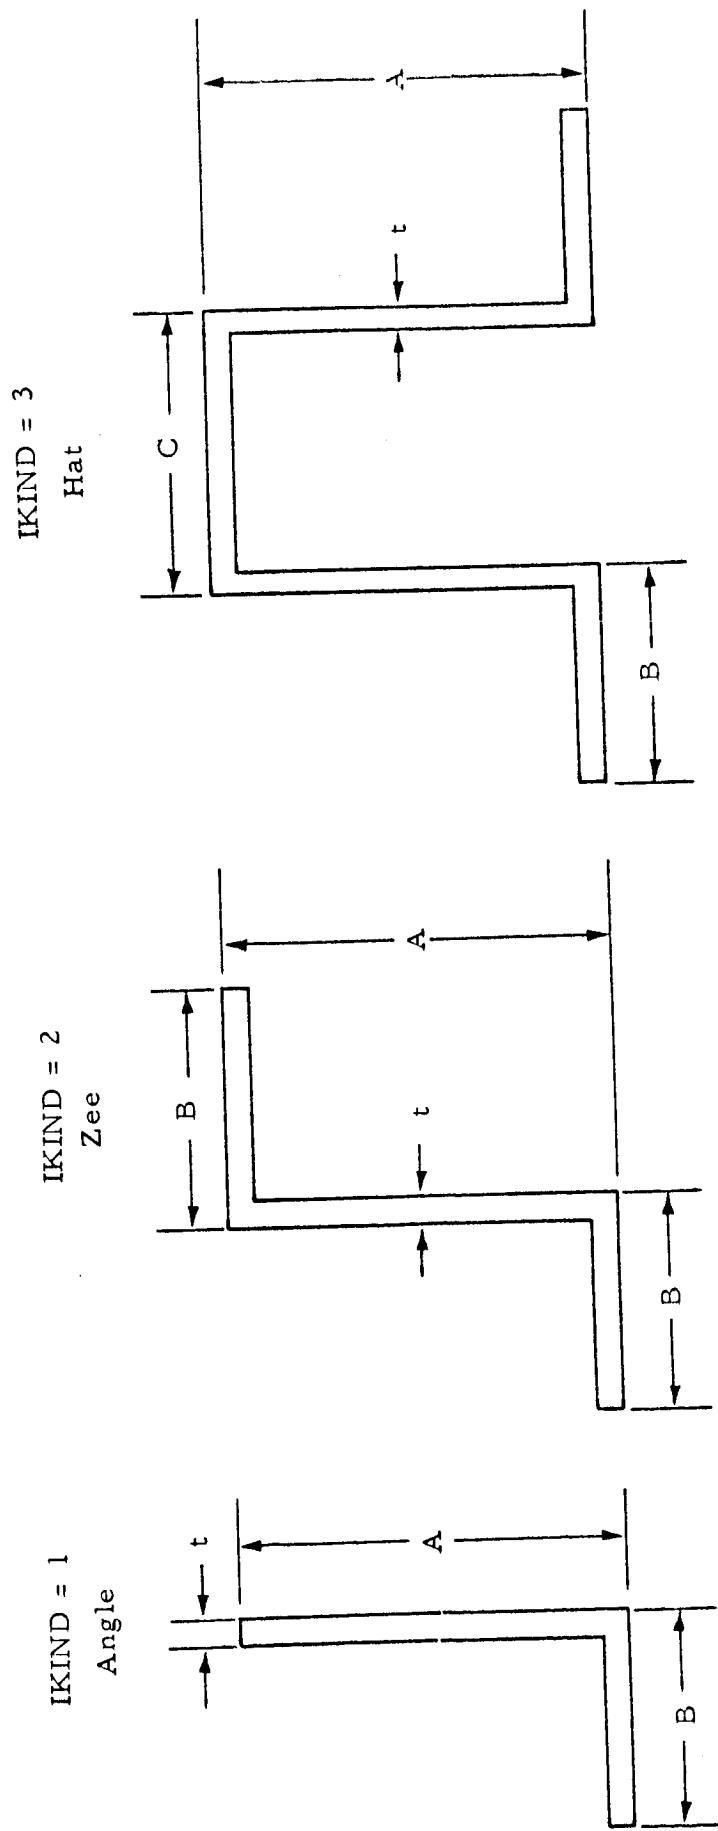

Figure 3 - Stiffener Cross-Section

commonly used variable names in this listing appear in Appendix B. The discussion which follows is supplemental to the information in the flow chart and program listing, and in general follows the sequence of the listing.

1.3 Required Input Data

The following input data is required by the computer program:

1. External fairing geometry (Figure 1)
2. Design specifications
 - a. Type of ring cross-section
 - b. Minimum distance between rings
 - c. Minimum skin gauge to be used for each frustum and the nose cap
 - d. Maximum skin temperature (if no value is input, the value stored in the program for the material specified will be used.)
3. Structural material (Properties for five materials are stored in the program. (See Section 1.5.)
4. Aerodynamic data at a design point in the trajectory
 - a. Mach number
 - b. Dynamic pressure
 - c. Angle of attack
 - d. Difference between internal pressure of fairing and free-stream pressure
5. Factor of safety (If no value is input a factor of 1.4 will be used.)
6. Program controls
 - a. Is pressure profile data input? If so, the type of lift data is indicated.
 - b. The desired type of output is indicated. (See Section 1.14)

- c. The magnitude of the increment to be used in perturbing bay length.
- 7. Pressure profile data (optional). If a pressure profile is not input, it is computed in Subroutine AERO.

Detailed instructions on how to input this data are provided in Section 3.

1.4 The Pressure Profile

Whether input or computed, the system used to specify the pressure profile in the axial direction on the section of fairing composed of conical frustums is illustrated in Figure 4. LT is an index indicating station number, starting with the first station at the junction of the nose cap and top frustum. Uniform spacing between stations is not necessary. Two stations must be located at each intersection of the conical frustums. Where discontinuities in the pressure profile exist, two stations can be indicated for the same location.

The following three parameters are required by the computer program at each station.

1. CPO (LT) - The pressure coefficient at zero angle of attack.
2. CPA (LT) - The difference between the pressure coefficient on the windward side when flying at an angle of attack and CPO (LT).
3. XOD (LT) - The axial distance measured from the tip of the nose cap divided by the fairing base diameter.

When the pressure profile is input to the program, three options are available for inputting lift data.

1. CPA (LT) as described above
2. CPA (LT) per radian angle of attack
3. $\frac{\partial}{(x/D)} \left(\frac{\partial C_N}{\partial \alpha} \right)$

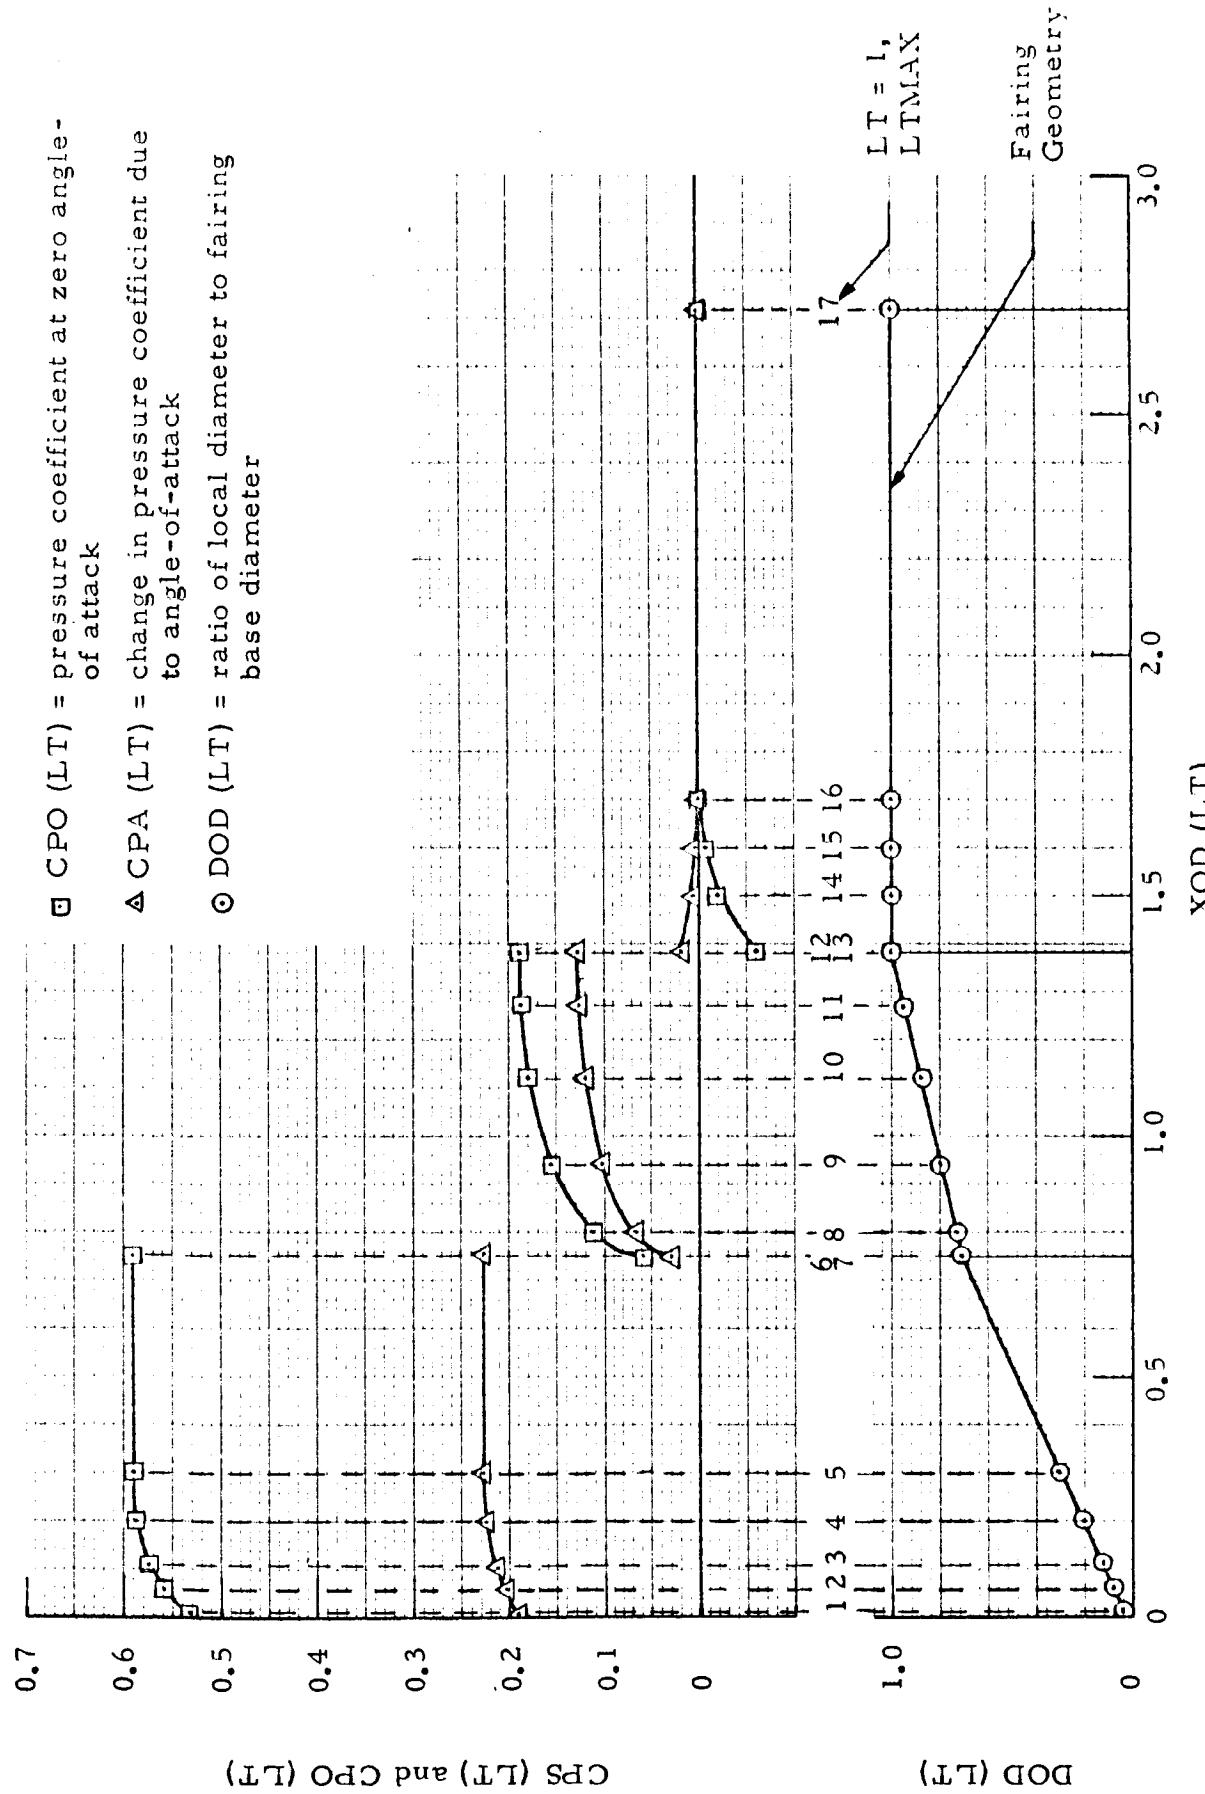

Figure 4 - Pressure Profile Used in Sample Problem

In option 3

C_N = the normal force coefficient with the fairing base as a reference area

α = angle of attack in radians

x/D = distance from the leading point in calibers

After they are read into the program, the lift data in Options 2 and 3 are converted to the form of Option 1. A sinusoidal pressure distribution (see Figure 5) in the circumferential direction is used in converting Option 3 to Option 1. Provisions can be made to read in other types of lift parameters, if the parameter can be converted to CPA (LT) after it is input.

The option is available to either compute or input axial force and lift data for the nose cap. In either case they are specified by the following three parameters:

1. Drag coefficient with the base area of the nose cap as the reference area
2. Normal force coefficient per radian angle of attack with the base area of the nose cap as a reference area
3. The location of the center of lifting pressure measured from the base of the nose cap.

1.5 Material Properties

Properties for the following five materials are now stored in the program in Subroutine PROPTY:

1. Aluminum
2. Magnesium
3. Titanium
4. Stainless steel
5. Lockalloy

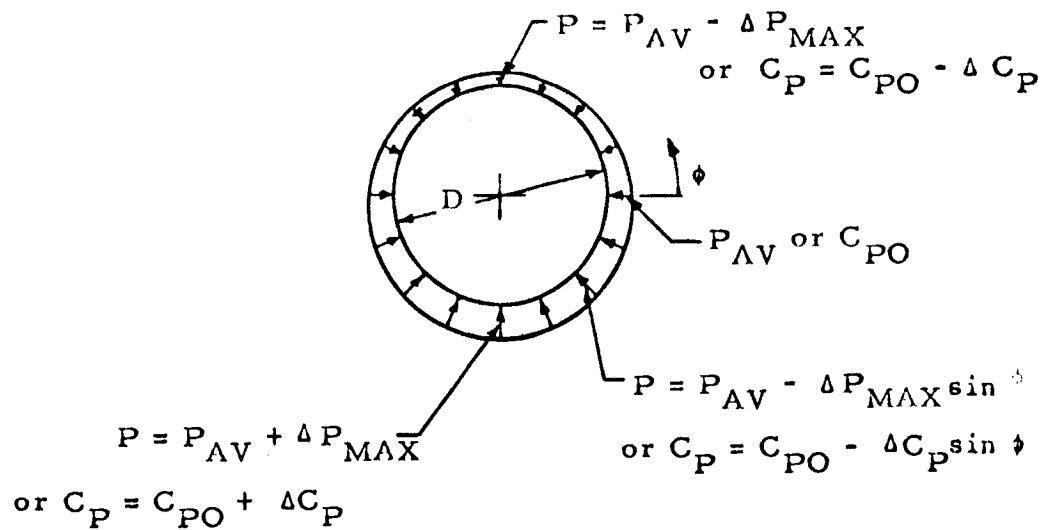

Figure 5 - Circumferential Pressure Distribution

Additional materials can be readily added to this list. Properties which are stored are as follows:

1. Modulus of elasticity
2. Poisson's ratio
3. Density
4. Maximum allowable temperature.

If a value is input for maximum allowable temperature the stored value is not used.

1.6 Thermal Considerations

The maximum temperature reached by the skin due to aerodynamic heating can be controlled by placing a lower limit on the skin thickness to be used in the nose cap and the top frustum. These minimum thicknesses are computed in Subroutine THERML. The minimum thickness computed for the nose cap is based on heating at the stagnation point, and the minimum thickness for the top frustum is based on heating at the point at which the nose cap is tangent to the top frustum. The equations in Subroutine THERML are based on a nominal trajectory of two-stage Saturn V vehicle ascending to a 100 nautical mile circular orbit.

1.7 Standard Skin Gauges

Only standard gauges are used in designing the shell portion of the bay and the stiffening ring. The stiffening ring cross-section has the shape shown in Figure 3. The standard gauges are listed in ascending order starting with 0.032 inch. (See BLOCK DATA subroutine in program listing in Appendix A.)

1.8 Design Loads

The individual bay is subjected to bending moments, axial forces and lateral pressure loads. Bending moments and axial forces at the base of the bay are computed in Subroutine LOAD, using the pressure profile data. These loads are then converted to line loads (force per unit of length on the circumference) on both the windward and leeward sides of the bay, and the factor of safety is applied.

The lateral pressure used in design of the bay is the difference between external and internal pressure multiplied by the factor of safety.

The maximum lateral pressures occurring along the length of the bay on both the windward and leeward sides are computed in Subroutine PRESUR, using pressure profile data and the input aerodynamic data.

1.9 The Weight Index (Does not apply to cylindrical sections.)

When designing a given bay; bay length, skin thickness and ring size can be varied within limits. A number of designs which will withstand the loading conditions are possible. In order to select a design as optimum it is necessary to have a measure of merit. In this program the measure of merit is the weight index -- the weight of the bay divided by its volume. The bay configuration having the smallest weight index is chosen as optimum.

The behavior of the weight index as the length of a typical bay is increased is shown in Figure 6. An abrupt change in the weight index occurs whenever an increase in skin gauge or ring gauge is necessary. The weight indexes computed by the program correspond to the low points on the curve. In general, the minimum weight index occurs at a relatively short bay length.

1.10 Estimation of Bay Lengths (Does not apply to cylindrical sections.)

Up to seven different skin gauges for each bay are considered in the search for the best design. For each skin gauge there is a bay length at which the skin stiffness is fully utilized. Because of the complexity of the equations it is necessary to determine this length by iteration. Much computer time can be saved by estimating this length before the iteration procedure is started.

After the first of the seven skin gauges has been established for a bay, the bay length associated with the next skin gauge is estimated by equations developed in Appendix I. One of the parameters in the computer program used to compute this approximate length is AK (J), which is defined as follows:

$$AK (J) = \left(\frac{T (J)}{T (J-1)} \right)^{3.28}$$

in which T (J) is the Jth stored standard skin gauge. AK (J) has been computed for each skin gauge listed (except the first) and stored in the program.

After assigning an approximate length to the bay, the design is checked, and length increments are either added or subtracted until the correct length is found.

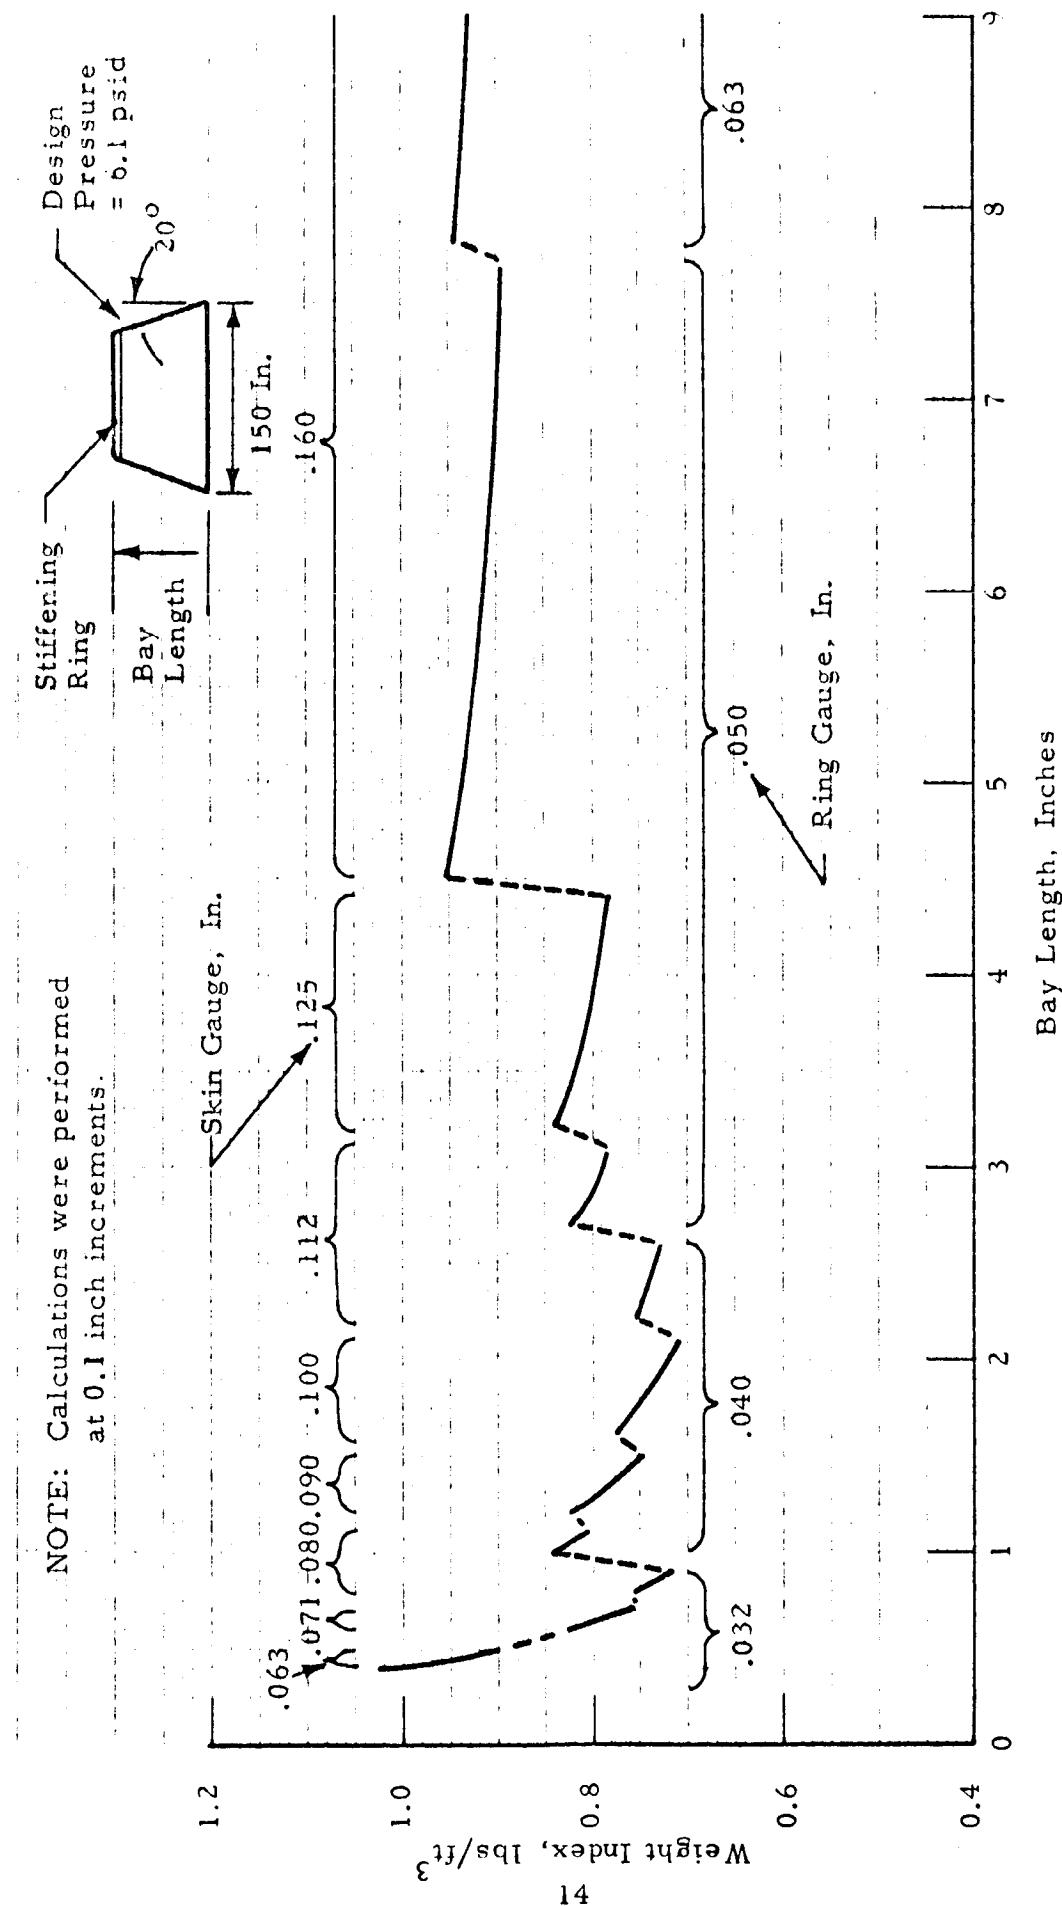

Figure 6 - Variation of Weight Index with Bay Length for a Typical Bay.

1.11 Last Bay in the Frustum (Does not apply to cylindrical sections.)

Before beginning the design of a bay, a check is made to determine if there is sufficient length remaining on the frustum for one more bay of minimum length. If there is not sufficient length for one more bay, the length of the last bay designed is added to the remaining undesigned length, and a routine is then begun to determine the minimum weight configuration of either one or two bays which completes the design of the frustum.

First, a check is made to determine if there is sufficient length remaining for two more bays of minimum length. If there is not sufficient space, one bay is designed, and the program goes on to the next frustum or the nose cap.

If there is enough space for two more bays, the program determines the weight of a number of two-bay configurations. While designing the last bay (the length of which was added to the undesigned length), the bay length and weight associated with each of the seven skin gauges were stored temporarily. These weights and lengths are now used for the first bays of the two-bay configurations. Weights of second bays, which fill out the frustum, are added to each of the first bay weights (within the constraint that second bays must be minimum length or longer). After exhausting these possibilities for two-bay configurations, the second bay length is set equal to minimum bay length, and the first and second bays are designed accordingly. Another possibility is to make one long bay. The weights of all of the above configurations are compared and the configuration having the smallest weight is chosen to fill out the frustum.

Additional weight is added to the top ring of each frustum to provide for attachment to the next frustum or nose cap. The magnitude of this additional weight in pounds is 10% of outside diameter of the ring in inches.

1.12 Nose Cap Design

Both structural and thermal requirements are considered in the design of the nose cap. The thickness required to limit the temperature to the specified maximum is computed in Subroutine THERML. (For details of the thermal analysis see Appendix J.) The thickness required to withstand aerodynamic loads is computed in Subroutine TNOSSST. (For details see Appendix H.) In both cases thickness is determined for conditions at the stagnation point. The greater of these two thicknesses is then used to design an unstiffened cap with uniform skin thickness. Nose cap skin thickness is not limited to standard gauges.

1.13 Design of Cylindrical Sections

On cylindrical sections of the fairing axial forces and bending moments are the predominant form of loading with lateral pressure playing a minor role. Whereas, on conical frustums, crushing pressure is likely to predominate. For this reason, the design procedure for the cylindrical sections differ from that of the conical frustums.

The design procedure for the cylindrical sections is based on A. B. Burn's adaptation of the Baruch-Singer General Instability Analysis (see Appendix K). This analysis assumes uniform skin thickness and equally spaced rings of uniform cross-section.

After determining the bay length which will give equally spaced rings without violating the minimum bay length constraint, the required skin thickness for the bottom bay of the cylindrical section is computed by the same methods used for the conical frustums (see Appendix F). The first value of the stored standard gauges is then assigned to the web thickness of the stiffeners ring. Assuming that this ring cross-section and the first bay loads and skin thickness prevail throughout the cylindrical section, the adequacy of the design is checked by Subroutine BARUCH. If the design fails, the ring web thickness is increased until the smallest standard gauge which provides a satisfactory design is found. This web thickness is then assigned to all rings in the cylindrical section.

Having determined the ring spacing and ring cross-section, skin thickness for each of the bays is computed by the same methods used for the conical frustums, using the loads acting on each of the bays.

1.14 Output Data

Three options are available on the amount of detail provided by the output data.

1. Design summary only (Figure 7A)
2. Design summary plus design details (Figure 7A, 7B and 7C)
3. Design summary plus design details plus loads details (Figures 7A, 7B, 7C and 7D).

Most of the headings appearing in the output are self-explanatory. However, there are several in Figure 7C and 7D which require some comment. Listed below for Figure 7C are several of the column headings and their definitions.

Weight Index

- Weight of the bay divided by the inclosed volume of the bay.

- | | |
|----------------------|--|
| Line Load | - Force per running inch of circumference, parallel to the skin surface, normal to the circumferential direction. A factor of safety has been applied to this force. |
| Stress Ratio, Axial | - The ratio of applied line load to the line load at which the skin buckles. |
| Stress Ratio, Press. | - The ratio of design pressure to the pressure at which the skin buckles. |
| Load Index | - A parameter which indicates that the skin design is satisfactory when it has a value equal to or less than 1.0. (See CHKWND and CHKLEE in Appendix B). |

In Figure 7D, the design pressures listed represent the maximum value occurring along the length of the bay. These values include the factor of safety. The axial load, skin load and bending moment listed occur at the base of the bay. These quantities do not include a factor of safety.

LOAD PLT. 7.3

Figure 7D - Computer Output for Sample Problem - Detailed Loads

2.0 DESCRIPTION OF SUBROUTINES

2.1 Subroutine THERML (Thermal Computations)

This subroutine computes the minimum thickness of skin required to limit the skin temperature to the specified maximum. Minimum thicknesses are computed for both the nose cap and top frustum. The analytical basis for the computations performed in Subroutine THERML is presented in Appendix J. The analysis is based on a nominal two-stage Saturn V ascent trajectory to a 100 nautical mile circular orbit.

The equations and stored coefficients in Subroutine THERML were developed by means of a multiple regression analysis of a large amount of analytical data generated for the trajectory mentioned above. Details of the multiple regression analysis are also presented in Appendix J.

The parameters required from the main program for computations in Subroutine THERML are RCAP, THETA, TMPMAX and MAT. Returned to the main program are TCONTH and TCAPTH.

2.2 Subroutine TNO SST (Nose Cap Structure)

Subroutine TNO SST calculates the nose cap skin thickness required to withstand the pressure differential, PDSPH, at the stagnation point. The method used to calculate PDSPH and the structural analysis of a spherical nose cap are described in Appendix H.

Parameters required by Subroutine TNO SST are PDSPH, E, RCAP and TMINN. Returned to the main program is TCAPST.

2.3 Subroutine AERO (Pressure Coefficients)

When a pressure profile is not input to the program the pressure coefficient data for the profile is computed in Subroutine AERO. The analytical basis for the computations performed in this subroutine is presented in Appendix C. Because of the assumptions made in computing this data, the pressure coefficient at zero angle of attack and the change in pressure coefficient due to angle of attack are uniform over the length of each frustum. The pressure profile is then constructed by assigning the pressure coefficient data for each frustum to the beginning and end points of each frustum. Double points occur at the intersection of two frustums.

Parameters required to make the computations in Subroutine AERO are NF, THTA (NF), AMACH and ALPHA. Returned to the main program are CPOO and CPAA.

A sinusoidal pressure distribution in the circumferential direction, such as that illustrated in Figure 6, is used in computing CPAA.

2.4 Subroutine LOAD (Bending Moment, Axial Force and Shear Force)

Using the pressure profile data, Subroutine LOAD computes the bending moment, axial force and shear force at the base of each bay. Bending moment and axial force are then converted to line loads (force per unit length of circumference) for both the windward and leeward sides of the bay, and the factor of safety is applied to these line loads.

When Subroutine LOAD is called upon for loads on the first bay, the bending moment, axial force and shear force are computed at the base of the fairing. As design of the fairing moves from the base to the nose cap, increments of the loads contributed by the pressure profile between the previous bay location and the new bay location are subtracted from the previous totals. Derivation of the equations used in this subroutine appear in Appendix D.

Information required for the computations in Subroutine LOAD is

1. Pressure profile data:

LTMAX

CPO (LT)	LT = 1, LTMAX
----------	---------------

CPA (LT)	LT = 1, LTMAX
----------	---------------

XOD (LT)	LT = 1, LTMAX
----------	---------------

2. Fairing geometry:

NFMAX

DBAS

ALF (NF)	NF = 1, NFMAX
----------	---------------

THTA (NF)	NF = 1, NFMAX
-----------	---------------

3. Aerodynamic data:

AMACH

QBAR

DELTAP

ALPHA

4. Miscellaneous:

DSUBB

C2

FS

LFLG

LTRIG

Parameters computed by Subroutine LOAD are ANFIMX, ANFIMN, FSUBZ and LTUNCT (NF) for NF = 1 to NFMAX.

2.5 Subroutine PRESUR (Lateral Pressure)

Using pressure profile data, Subroutine PRESUR computes the pressure differential across the skin along the length of the bay. The maximum differential occurring along the bay length is determined for both the windward and leeward sides, multiplied by the factor of safety and returned to the main program. The equations used in this subroutine are developed in Appendix E.

Parameters required for computations performed in Subroutine PRESUR are

1. Pressure profile data

LTMAX

CPO (LT) LT = 1, LTMAX

CPA (LT) LT = 1, LTMAX

XOD (LT) LT = 1, LTMAX

2. Other parameters: LPFL, C2, DBAS, DSUBB, ALB, QBAR, NFMAX, NF, DELTAP, FS and LTUNCT (NF) for NF = 1 to NFMAX.

Parameters computed in Subroutine PRESUR are PDESMN, PDESMX, ALN and ALX.

2.6 Subroutine CHKL0D (Checks Adequacy of Skin Design)

When given the line loads, lateral pressure, geometry of the bay and skin thickness, Subroutine CHKL0D determines whether the skin is thick enough. The criteria used to appraise the design are presented in Appendix F.

Parameters required to perform the computations in Subroutine CHKL0D are DSUBB, DELTAS, ALB, C1, C2, C3, C4, ANFIMN, ANFIMX, E, PDESMN and PDESMX.

Parameters computed in Subroutine CHKL0D are RPMIN, RPMAX, RAXMIN, RAXMAX, CHKWND, CHKLEE, and CHK.

2.7 Subroutine DIAM (Local Diameter)

When given the parameters describing the external geometry of the fairing and the distance from the tip of the nose cap in calibers this subroutine computes the local fairing diameter.

Parameters required by this subroutine are:

ALTOT

ALF (NF), NF = 1, NFMAX

THTA (NF), NF = 1, NFMAX

DMN (NF), NF = 1, NFMAX

XN

NFMAX

The local diameter, DLOC, is computed by this subroutine.

2.8 Subroutine DLOD (Incremental Loads)

When given the geometry and pressure coefficient data for an incremental length of the fairing this subroutine computes the contribution by this increment to the total bending moment, axial load and shear load.

Input parameters are XOD1, XOD2, D1, D2, CP01, CP02, CPA1, CPA2, A3, A4, and DP.

Parameters computed in Subroutine DLOD are FSBZ, BND, and AXLOD.

2.9 Subroutine RING (Ring Strength and Stiffness)

When given the cross-sectional shape of the ring and the skin gauge from which is to be fabricated this subroutine computes the moment of inertia of the ring with and without the effective skin, its cross-sectional

area, eccentricity and torsion constant. This subroutine also calls Subroutine RSTRES which computes the local stress level in the ring.

Input parameters required by RING are E, IKIND, AOT, BOT, COT, WSEF, J, K, PI, and T(J) when J = 1, 30.

Output parameters are AIRING, AISTT, AST, A, Z, ECC and TCONST.

2.10 Subroutine RSTRES (Local Stress Level in Ring)

When designing a stiffener ring it is necessary to check for local instability in the ring flange or web (see Appendix G). Subroutine RSTRES computes the local stress level in the ring. This computed stress level is then compared to an input flange buckling stress level, and, if necessary, a greater web thickness is assigned to the ring.

Input parameters for Subroutine RSTRES are A, T(J), Z, PDESMX, DSUBB, CTH, AL(J), AST, and AISTT.

The output parameter is FRING.

2.11 Subroutine IREQ (Required Moment of Inertia)

This subroutine computes the stiffening ring moment of inertia requirements to prevent general instability of the structure. The methods used to compute this required moment of inertia are described in Appendix G.

Input parameters are THTA (NF), C6, AL(J), DSUBB, C2, PDESMX, T(J), PI, ANFIMX, E and ALCONE.

The output parameter is AIREQ.

2.12 Subroutine PROPTY (Material Properties)

Properties of several commonly used materials are stored in this subroutine.

The material for which properties are desired is indicated by the input parameter MAT.

Output parameters are the material properties E, AMU, RHO, and TMPMAX.

2.13 Subroutine BARUCH (Designs Rings for Cylindrical Sections)

When given a skin gauge, crushing pressure, ring spacing and ring cross-section, Subroutine BARUCH computes the line load at which general instability of the composite structure of a cylindrical section occurs. The procedure followed in designing a cylindrical section is discussed in Section 1.13, and Burn's adaption of the Baruch-Singer analysis (which is used in Subroutine BARUCH) is discussed in Appendix K.

Subroutine BARUCH requires a large amount of tabular information which, for reasons of convenience, is read into the program as regular input data. This data is physically located immediately after the program deck followed by a comment card stating, "END OF BARUCH-SINGER DATA CARDS -- BEGIN NOSE FAIRING DATA CARDS." Nose fairing data cards for a number of nose fairing designs can be stacked in the usual manner after this comment card.

The complete Baruch-Singer analysis as used in this program consists of five subroutines. However, all communication with the main program is channeled through Subroutine BARUCH. Input parameters required by Subroutine BARUCH are AST, ECC, AIST, DY, DELTAS, AMU, E, RCYL, ALF (NF), TCONST and either PDESMN when checking the design on the leeward side or PDESMX when checking the design on the windward side.

The output parameter from Subroutine BARUCH is ANFICR, the line load at which failure will occur.

3.0 INPUT FORMAT

In addition to the data cards required by Subroutine BARUCH (see Section 2.13), which should be considered a permanent part of the program, input data describing the fairing to be designed is required by the program. These nose fairing data cards should be physically located after the comment card stating "END OF BARUCH-SINGER DATA CARDS -- BEGIN NOSE FAIRING DATA CARDS." A number of nose fairing design cases can be stacked in the usual manner after this comment card.

When the pressure profile and nose cap lift and drag data are to be computed in the program, the following three types of input data cards are the only types required.

Types 1 and 2. Parameters which apply to the entire fairing.

Types 3 and 4. Parameters which apply to individual frustum (one of each per frustum).

When lift and drag data for the nose cap are to be input, or when a pressure profile is to be input, the following additional card type is required.

Type 5. Lift and drag data for the nose cap.

When pressure profile data is to be input, two additional card types are required.

Type 6. Pressure profile data points (one card per data point).

Type 7. Card indicating end of pressure profile data.

The detailed format for these cards is as follows:

Type 1: Format (5 F 12.8, I 12)

Data:	DBAS	- Base diameter of fairing, in.
	DELTAL	- Increment by which bay length is changed during design iteration (usually 0.1 inches), in.
	QBAR	- Dynamic pressure at design point in the trajectory, lbs/sq. ft.
	AMACH	- Mach number at design point in the trajectory.
	ALPHA	- Angle of attack at design point in the trajectory, degrees.
	KEY	- An integer indicating the type of output desired. The code is as follows:

- (0) Design summary only. (See Figure 7A).
- (1) Design summary plus design details (Figures 7A, 7B, and 7C).
- (2) Design summary plus design details plus load details (Figures 7A, 7B, 7C and 7D).

Type 2: Format (2I6, 4F12.8, I12)

Data:	MAT	- An integer indicating the material to be used. The code is as follows:
		(1) aluminum
		(2) magnesium
		(3) titanium
		(4) stainless steel
		(5) Lockalloy (a Be-Al alloy)
	NFMAX	- The number of conical frustums in the fairing.
	TMP	- The maximum allowable skin temperature for the nose cap and top frustum, °F. (If no value is input, the value stored with the material properties is used. If a value equal to or greater than 10,000 is input, no thermal constraint is imposed on the skin thickness.)
	TMINN	- The minimum skin gauge to be used in nose cap design, in.
	DELTAP	- Difference between internal and free-stream pressure, psi
	FS	- Factor of safety. (If no value is input, a factor of safety of 1.4 is used.)
	LPRES	- An integer indicating whether nose cap lift and drag data and/or pressure profile data will be input. If pressure profile data is input, LPRES also indicates the type of lift data to be input. The code is as follows:

- (-1) Lift and drag data for the nose cap is input, but no pressure profile data is input.
- (0) No nose cap or pressure profile data is input.
- (1) Nose cap data and pressure profile data with CPA (LT) as defined in Figure 5 and Appendix B is input on Card type 5.
- (2) Same as (1) except that CPA (LT) per radian angle of attack is input for CPA (LT) on Card type 5.
- (3) Same as (1) except that

$$\frac{\partial}{\partial \alpha} \left(\frac{\partial C_N}{\partial \alpha} \right) \quad (\text{See Section 1.4}) \text{ is input for CPA (LT) on Card type 5.}$$

(One Type 3 and Type 4 card is required for each frustum.)

Type 3: Format (4F12.8)

Data: ALF (NF)	- Ratio of top diameter of frustum to base diameter of fairing or length of the frustum in inches. If the number is equal to or greater than 1, it will be treated as frustum length. For conical sections, either the diameter ratio or length can be used. For cylindrical sections, only length can be input.
THTA (NF)	- Frustum half angle, degrees.
ELMIN (NF)	- Minimum bay length to be used in designing frustum, in.
TMNC (NF)	- Minimum skin thickness to be used in designing frustum, in.

Type 4: Format (I5, 6E12.8)

Data: IKIND	- Indicates shape of stiffener ring (see Figure 3 for code).
AOT	- The ratio A/t (see Figure 3).
BOT	- The ratio B/t (see Figure 3).

- COT - The ratio C/t (see Figure 3).
 FCFB - Ring outstanding flange buckling level, PSI.

The next card type is required only when nose cap lift and drag data or a pressure profile is read in (LPRES = -1, 1, 2 or 3 in Card Type 2). If a blank card is inserted for Card Type 5 when LPRES = 1, 2 or 3, the program will compute CDCAP, CNCAP and XBCAP.

Type 5: Format (3F12.8)

- Data: CDCAP - Spherical nose cap drag coefficient with nose cap base area as a reference area.
 CNCAP - Normal force coefficient per radian angle of attack for the nose. Reference area is nose cap base area.
 XBCAP - Distance from base of nose cap to center of pressure for the nose cap, in.

The next two card types are required only when pressure profile data is input (LPRES = 1, 2 or 3). (See Section 1.4 and Figure 4.)

Type 6: Format (3F12.8)

- Data: CPO (LT) - Zero angle of attack pressure coefficient at station LT.
 CPA (LT) - Lift parameter at station LT. See LPRES on Card Type 2 and Section 1.4 for options which are available.
 XOD (LT) - Axial distance from nose in calibers.

(One card is required for each data point, starting with the first point at the junction of the nose cap and top frustum.)

Type 7: Format (71X, 11)

- Data: LSTOP = 1 - This signals the computer that the last pressure profile data point has been read in.

The set of data cards described above will design one fairing. A number of fairings can be designed with one computer run by placing several sets of data cards behind the program deck.

4.0 SAMPLE PROBLEM

The following sample problem illustrates the input format of the program. Input data is as follows:

Fairing geometry:

DBAS	= 260.0 inches
NFMAX	= 3
ALF (1)	= 349.0 inches
ALF (2)	= 0.72
ALF (3)	= 0.03
THTA (1)	= 0.00 degrees
THTA (2)	= 12.5 degrees
THTA (3)	= 25.0 degrees

Design specifications:

ELMIN(1)	= 16.0 inches
ELMIN(2)	= 16.0 inches
ELMIN(3)	= 16.0 inches
TMNC(1)	= 0.032 inches
TMNC(2)	= 0.032 inches
TMNC(3)	= 0.032 inches
TMINN	= 0.032 inches
TMP	= 600.0 °F

One ring shape is specified for all three frustums.

IKIND	= 2
AOT	= 20.0
BOT	= 10.0
COT	= 0.0
FCFB	= 30000.0 psi

Material:

MAT	= 1 (aluminum)
-----	----------------

Aerodynamic data:

AMACH	= 1.5
QBAR	= 765.0 lbs/sq ft
ALPHA	= 8.5 degrees
DELTAP	= 0. psi

Factor of Safety:

FS	= 1.4 (It is not necessary to input this value, since 1.4 is the value which the program uses when no value is indicated.)
----	--

Program Controls:

LRES = 1
KEY = 2
DELTAL = 0.1 inches

Nose cap lift and drag data:

A blank card is inserted in the deck in place of Card Type 5, causing the program to compute this data.

Pressure profile data:

Data for the pressure profile is taken from Figure 4 and listed in Figure 8 under Card Type 6.

This input data is arranged in key-punch format in Figure 8. The computer output for this problem is shown in Figures 7A, 7B, 7C and 7D.

C
C PROGRAM FOR GEN INST ANALYSIS OF RING-STIFFENED CYLINDERS
C THIS PROGRAM HANDLES AXIAL COMPRESSION PLUS LATERAL PRESSURE
C THE CYLINDER WALL IS ASSUMED TO BE NON-BUCKLING TO ULTIMATE LOAD
C THE RINGS ARE EQUALLY SPACED, AND OF IDENTICAL CROSS SECTION
C THE RINGS ARE INSIDE
C
C THIS IS AN ELASTIC ANALYSIS
C THIS PROGRAM BASED ON BARUCH-SINGER EQUATIONS WITH KNOCKDOWN
C FACTOR BASED ON (R/T)EFF APPLIED TO CLASSICAL
C BUCKLING LOAD SO OBTAINED
C
C SUBROUTINES CRIT, TERP4, TERP5 AND TERP7, WHICH FOLLOW THIS
C SUBROUTINE, ARE PART OF THE BARUCH-SINGER ANALYSIS.

APPENDIX B

DEFINITIONS OF VARIABLE NAMES

A	-	Ring cross-sectional dimension (see Figure 3), in.
AC	-	Area of the base of the spherical nose cap, sq. in.
AIST	-	Moment of inertia of ring, in. ⁴
AISTT	-	Moment of inertia of ring and effective skin, in. ⁴
AINDEX(J)	-	Weight index (weight of bay divided by volume of bay), lbs/cu in.
AIREQ	-	Moment of inertia required of the stiffening ring cross-section, in. ⁴
AIRING	-	Moment of inertia of the stiffening ring, in. ⁴
AK(J)	-	A factor used in making a first estimate of bay length when increasing skin thickness from T (J-1) to T (J).
AL(J)	-	Bay length, in.
ALI(J)	-	Length of next to last bay in frustum, in.
ALB	-	Bay length, in.
ALCAP	-	Axial length of nose cap, in.
ALCONE	-	Frustum length, in.
ALF (NF)	-	Length of frustum number NF, in.
ALMAX	-	Maximum bay length. (For the first three skin gauges tried, ALMAX is equal to ALMX 2, and for the last four skin gauges ALMAX is equal to either ALMX1 or ALMX2, whichever is less.) in.
ALMIN	-	Minimum length specified for bay, in.
ALMN	-	Either ALMIN or the bay length computed for next smaller skin gauge, whichever is greater, in.
ALMXI	-	ALMIN plus 40 inches, in.
ALMX2	-	Axial distance from base of bay to top of frustum, in.
ALN	-	Axial distance from base of bay to point at which lateral pressure on the leeward side of the bay is greatest, in.
ALPHA	-	Angle of attack, degrees when read in and radians when used in computations.

ALOPT(I)	- Optimum length for Ith bay, in.
ALTOT	- Total length of fairing, in.
ALX	- Axial distance from base to bay to point at which the lateral pressure on the windward side is a maximum, in.
AMACH	- Mach number.
AMU	- Poisson's ratio.
ANFIAL	- Maximum allowable line load for a given bay configuration, lbs/in.
ANFIAX	- Line load contributed by axial loading on bay, lbs/in.
ANFIB	- Line load contributed by bending moments on bay, lbs/in.
ANFICR	- Critical line load, lbs/in.
ANFIMN	- Total line load on windward side of fairing multiplied by factor of safety, lbs/in.
ANFIMX	- Total line load on leeward side of fairing multiplied by factor of safety, lbs/in.
AOT	- The ratio A/t (see Figure 3)
AS	- A coefficient determined by "least squares" techniques for the linear equation representing heat input to the nose cap skin at the stagnation point.
AST	- Cross-sectional area of ring, sq in.
AT	- A coefficient determined by "least squares" techniques for the linear equation representing heat input to top frustum skin at its junction with the nose cap.
AXLDCP	- Axial load contributed by nose cap, lbs.
AXLOAD	- Axial load at some specified location on fairing, lbs.
AXLOD	- Axial load contribution of a segment of the pressure profile, lbs.
BEND	- Bending moment at some specified location on fairing, lbs/in.
BND	- Bending moment of a segment of the pressure profile computed about the point on the segment nearest the fairing base, lbs-in.
BNDCAP	- Bending moment of the nose cap about its base, lbs-in.

BOT	-	The ratio B/t (see Figure 3)
C1	-	A constant defined by Line No. RS202630 of the program listing in Appendix A.
C2	-	A constant defined by Line No. RS202640 of the program listing in Appendix A.
C3	-	A constant defined by Line No. RS202650 of the program listing in Appendix A.
C4	-	A constant defined by Line No. RS201540 of the program listing in Appendix A.
C5	-	A constant defined by Line No. RS202660 of the program listing in Appendix A.
C6	-	A constant defined by Line No. RS202670 of the program listing in Appendix A.
C7	-	A constant defined by Line No. RS202680 of the program listing in Appendix A.
CDCAP	-	Drag coefficient for the spherical nose cap with the base area of the nose cap as a reference area.
CHK	-	A parameter computed in Subroutine CHKL0D which indicates the adequacy of the design. The code is as follows: 1.0 More than adequate 0.0 Adequate -1.0 Less than adequate
CHKLE(I)	-	A parameter computed in Subroutine CHKL0D which indicates the adequacy of the design on the leeward side of fairing. The design is adequate when CHKLE(I) is equal to or less than 1.0.
CHKLEE	-	Same as CHKLE(I).
CHKWD(I)	-	A parameter computed in Subroutine CHKL0D which indicates the adequacy of the design on the windward side of the fairing. The design is adequate when CHKWD(I) is equal to or less than 1.0.
CHKWND	-	Same as CHKWD(I).

CL	-	A constant defined by Line No. RS204180 of the program listing in Appendix A.
CNCAP	-	Normal force coefficient per radian angle of attack for the spherical nose cap using nose cap base area as a reference area, /radian.
CPA(LT)	-	The change in pressure coefficient on either the windward or leeward side of the fairing due to angle of attack at station LT. (See Figures 4 and 5.)
CPAA	-	Same a CPA(LT).
CPMN	-	Pressure coefficient on the leeward side of the fairing.
CPMX	-	Pressure coefficient on the windward side of the fairing.
CPO(LT)	-	Pressure coefficient at zero angle of attack at station LT.
CPOO	-	Same as CPO(LT).
CPSTG	-	Pressure coefficient at stagnation point of the nose cap.
CSUBP	-	Coefficient of critical buckling pressure (See Equation F5 in Appendix F.)
CTH	-	Cosine of THETA.
CZALFA	-	Normal force coefficient per radian angle of attack.
D (I)	-	Small diameter of the Ith bay, in.
DBAS	-	Base diameter of fairing, in.
DBASE	-	Base diameter of a frustum, in.
DELTA	-	Same as THETA.
DELTAL	-	Increment by which bay length is perturbated while designing a bay, in.
DELTAP	-	Difference between internal and free-stream pressure, psi.
DELTAS	-	Bay skin thickness, in.

DMIN	-	Small diameter of frustum, in.
DMN(NF)	-	Small diameter of frustum number NF, in.
DUSEI	-	Diameter of area useful for payload at the base of the bay. (See Line RS207420 of program listing in Appendix A.)
DUSE2	-	Diameter of area useful for payload at top of bay. (See Line RS207430 of program listing in Appendix A.)
DSUBB	-	Base diameter of bay, in.
DY	-	Bay length, in.
E	-	Modulus of elasticity of structural material, in.
ECC	-	Distance from ring centroid to skin centerline, in.
ELMIN(NF)	-	Minimum bay length for frustum NF, in.
ENFIMN (I)	-	ANFIMN for Ith bay, lbs/in.
ENFIMX (I)	-	ANFIMX for Ith bay, lbs/in.
FCFB	-	Maximum allowable local stress in ring, psi.
FCCR	-	Compressive stress at which skin buckles in the absence of other loading, psi.
FRING	-	Local stress in ring, psi.
FS	-	Factor of safety.
FSBZ	-	Shear force contributed by an increment of pressure profile, lbs.
FSBZCP	-	Shear force contributed by nose cap, lbs.
FSUBZ	-	Shear force at a specified location on the fairing, lbs.
FZ (I)	-	Shear force at the base of the Ith bay, lbs.
HUSE	-	Useful axial length of nose cap (see Line No. RS209670 in Appendix A), in.
IKIND	-	Code number for ring cross-sectional shape. (See Figure 3.)
IMAX	-	Total number of bays in fairing.

IMX(NF)	-	Number of bays from bottom of fairing to top of frustum NF.
IW	-	Index indicating bay number within a frustum.
J	-	Index indicating parameter associated with skin thickness T (J).
JF	-	Index of skin thickness which is optimum for a bay.
JMIN	-	Index of the smallest skin thickness which is equal to or greater than the minimum thickness specified.
K	-	Index indicating ring parameters associated with a ring using thickness T (K).
KEY	-	Input parameter indicating type of output desired. (See Section 3.0 of the TECHNICAL DISCUSSION.)
LAST	-	An index used to identify a particular two-bay configuration designed to complete a frustum.
LFLAG	-	An integer used to control manipulation of candidate configurations for completing the design of a frustum.
LFLG	-	An integer used to control computation of loads during completion of frustum design.
LPFL	-	An integer used to control computation of lateral pressures.
LPRES	-	An integer indicating type of pressure profile to be read in. (See Section 3.0 of TECHNICAL DISCUSSION.)
LSTOP	-	An integer indicating that the last pressure profile data card has been read.
LTMAX	-	Total number of pressure profile data points.
MAT	-	An integer indicating the material to be used. (See Section 3.0 of the TECHNICAL DISCUSSION.)
NBAY	-	Number of bays in a frustum.
NF	-	Index indicating frustum number.

NFMAX	-	Total number of frustums in the fairing.
OMEGA	-	Defined in Line No. RS213660 in the program listing in Appendix A.
PCOLL	-	Pressure at which nose cap structure will collapse, psi.
PCRT	-	Lateral pressure at which skin buckles in the absence of other loading, psi.
PDESMN	-	Maximum pressure differential across the skin, multiplied by the factor of safety, on the leeward side of the bay, psi.
PDESMX	-	Maximum pressure differential across the skin, multiplied by the factor of safety, on the windward side of the fairing, psi.
PDSPH	-	Maximum pressure differential across the nose cap skin, multiplied by a factor of safety, psi.
PSTAT	-	Free-stream pressure, psi.
QB	-	Dynamic pressure, psi.
QBAR	-	Dynamic pressure, lbs/sq. ft.
RAXMAX	-	ANFIMX/ANFIAL
RAXMIN	-	ANFMN/ANFIAL
RAXMN(I)	-	RAXMIN for the Ith bay.
RAXMX(I)	-	RAXMAX for the Ith bay.
RCAP	-	Radius of spherical nose cap, in.
RCYL	-	Radius of cylindrical section, in.
RHO	-	Material density, lbs /cu. in.
RPMAX	-	PDESMX/PCRT
RPMIN	-	PDESMN/PCRT
RPMN (I)	-	RPMIN for the Ith bay.

RPMX (I)	-	RPMAX for the Ith bay.
RUSE	-	Radius of nose cap volume which is useful for payload. (See Line No. RS209660 of the program listing in Appendix A.), in.
SCAP	-	Surface area of spherical nose cap, sq. in.
SLOPT	-	Sum of bay lengths within a frustum, in.
STH	-	Sine of THETA.
SUMAL	-	Distance from the base of the fairing to the base of the bay, in.
T (J)	-	A standard skin gauge stored in the program, in.
TCAP	-	Thickness of nose cap skin, in.
TCAPST	-	Thickness of nose cap skin required to withstand pressure loads, in.
TCAPTH	-	Thickness of nose cap skin required to limit its temperature to the maximum specified, in.
TCONST	-	Torsion constant of ring, in. ⁴
TCONTH	-	Thickness of skin required on the top frustum to limit its temperature to the maximum specified, in.
THETA	-	Frustum half angle, radians
THTA(NF)	-	Half angle of frustum NF, degrees.
TMINC	-	Minimum skin thickness to be used in designing a frustum, in.
TMINN	-	Minimum skin thickness to be used in designing the nose cap, in.
TMNC(NF)	-	TMINC for frustum NF, in.
TMP	-	Maximum allowable temperature for both the top frustum and nose cap, °F.
TMPMAX	-	Same as TMP.

TR (J)	-	Thickness of ring material required with a bay design using a skin thickness of T (J), in.
TRING (I)	-	Thickness of ring material for optimized design of the Ith bay, in.
TSKIN (I)	-	Thickness of skin for optimized design of the Ith bay, in.
TT	-	Ring web thickness, in.
VCAP	-	Volume of nose cap which is useful for payload (see HUSE and RUSE), cu. ft.
VGROSS	-	Gross volume of fairing, cu. ft.
VSEG (J)	-	Volume of bay designed for a skin gauge of T (J), cu. in.
VTOT	-	Useful volume of fairing (see DUSE1, DUSE2, HUSE and RUSE), cu. ft.
VUSE	-	Useful volume of frustum (see DUSE1 and DUSE2), cu. ft.
WCAP	-	Weight of nose cap, lbs.
WCONE	-	Frustum weight, lbs.
WR (J)	-	Weight of ring when the skin gauge for the bay is T (J), lbs.
WRING (I)	-	Weight of ring for the Ith bay, lbs.
WS (J)	-	Weight of skin for bay design using skin gauge T (J), lbs.
WSEF	-	Width of skin which contributes to ring stiffness, in.
WSEG (J)	-	Weight of bay when bay is designed using a skin gauge of T (J), lbs.
WSKIN (I)	-	Weight of skin for optimized design of the Ith bay, lbs.
WT (LAST)	-	Weight of two-bay configuration required to complete the design of a frustum, lbs.
WTDEX (I)	-	Weight index, weight to volume ratio for the optimized design for the Ith bay, lbs/cu. ft.
WTOT	-	Total fairing weight, lbs.

- X - Length of pressure profile increment, in.
- XBCAP - Distance from base of nose cap to center of lift pressure on the nose cap, in.
- XOD(LT) - Axial location measured from the forward-most point on the nose divided by base diameter.

APPENDIX C
AERODYNAMIC PRESSURE COEFFICIENTS

When data for the fairing pressure profile is not input, the pressure coefficient at zero angle of attack, CPOO, and the maximum change in pressure coefficient due to angle of attack, CPAA, are computed for each conical frustum in Subroutine AERO. For the purpose of computing these parameters, each frustum is treated as a complete cone with an attached shock. Both CPOO and CPAA will then be uniform in the axial direction for each frustum. In order to construct the pressure profile as described in Section 1.4 and Figure 4, the values computed for CPOO and CPAA for the frustum are assigned to the stations at the ends of the frustum. That is

$$\begin{aligned} CPO(LT) &= CPOO \\ CPO(LT+1) &= CPOO \\ CPA(LT) &= CPAA \\ CPA(LT+1) &= CPAA \end{aligned}$$

In which LT is the station at the small diameter of the frustum, and (LT+1) is the station at the large diameter of the frustum.

Using the ground rules indicated above, CPOO can be readily determined through the use of equations developed by Simon and Walter in Reference 2, which agree within a few percent with data presented in Chart 6 of Reference 3 (NACA Report 1135). These equations have been programmed in Subroutine AERO and are used in computing CPOO for each frustum.

When flying at an angle of attack the pressure distribution in the circumferential direction varies with circumferential position. This circumferential pressure distribution is assumed to be sinusoidal (see Figure 5). Since each frustum is treated as a complete cone, the distribution in the axial direction is uniform. The pressure distribution over the entire frustum can now be described by equations specifying the circumferential pressure distribution. These equations, as illustrated in Figure 5, are

$$C_P = C_{PO} - \Delta C_P \sin \phi \quad (C1)$$

$$P = P_{AV} - \Delta P_{MAX} \sin \phi \quad (C2)$$

In which

$$C_{PO} = CPOO$$

$$\Delta C_P = CPAA$$

The normal force, ΔF_N , produced on an incremental length, ΔX , by this pressure distribution can be computed as follows:

$$\Delta F_N = \Delta X \int_0^{2\pi} (-P \sin \phi) \left(\frac{D}{2}\right) d\phi \quad (C3)$$

in which D is the diameter of the increment. When the expression for P (Equation C2) is substituted in Equation C3, and the integration performed

$$\Delta F_N = \frac{\pi}{2} D (\Delta X) (\Delta P_{MAX}) \quad (C4)$$

In which

$$\Delta P_{MAX} = (\Delta C_P) q$$

and

$$\Delta F_N = \frac{\pi}{2} D (\Delta X) (\Delta C_P) q \quad (C5)$$

The normal force on the same increment of cone can also be computed by using the normal force coefficient, C_N . For a complete cone the normal force, F_N , is expressed by

$$F_N = C_N q A \quad (C6)$$

in which A is the base area of the cone. The incremental normal force, ΔF_N , produced by a short length, ΔX , of this cone is

$$\Delta F_N = C_N q (\Delta A) \quad (C7)$$

in which ΔA is the surface area of the increment projected on the cone base, expressed by

$$\Delta A = \frac{\Delta D}{2} (\pi D) \quad (C8)$$

The change in diameter, ΔD , for a change in length, ΔX , is

$$\Delta D = 2 (\Delta X) \tan \theta \quad (C9)$$

in which θ is the half angle of the cone. Substituting Equations C8 and C9 into C7 yields the following expression for ΔF_N :

$$\Delta F_N = C_N q (\pi D) (\Delta X) \tan \theta \quad (C10)$$

When the two expressions for ΔF_N (Equations C5 and C10) are equated and solved for ΔC_P , the following expression is obtained.

$$\Delta C_P = 2 C_N \tan \theta \quad (C11)$$

In Chart 8 of Reference 3 $C_{N\alpha}$ is plotted as a function of cone half angle θ and Mach number. $C_{N\alpha}$ is defined as

$$C_{N\alpha} = \left(\frac{\partial C_N}{\partial \alpha} \right)_{\alpha=0} \quad (C12)$$

in which α is the angle of attack. For small angles of attack the following relationship is valid:

$$C_N = (C_{N\alpha})\alpha \quad (C13)$$

For the study for which this computer program was developed maximum loads occur in the neighborhood of Mach 1.5. In this region $C_{N\alpha}$ is not a strong function of Mach number. Therefore, a plot was made of $C_{N\alpha}$ versus θ at Mach 1.5. The points fell on a straight line expressed by the following equation.

$$C_{N\alpha} = 2.03 - 1.2\theta \quad (C14)$$

In Equation C14 both α and θ are expressed in radians. Substituting Equations C13 and C14 into C11 yields the following equation which is used to compute CPAA in Subroutine AERO ($CPAA = \Delta C_P$).

$$\Delta C_P = (2 \tan \theta) (2.03 - 1.2\theta)\alpha \quad (C15)$$

In Equation C15, ΔC_P is the difference between the pressure coefficient on the windward side of the fairing and the pressure coefficient at the neutral position on the fairing.

APPENDIX D

BENDING MOMENTS, AXIAL LOADS AND SHEAR LOADS

In order to design a bay within the nose fairing structure, it is necessary to know the magnitude of the loads to which the bay is subjected. In addition to lateral pressure there are bending moments and axial loads which are used in computing line loads (force per running inch on the circumference) for the bay being analyzed. These computations are performed in Subroutine LOAD using the pressure profile data which was either computed in Subroutine AERO or input to the program.

The pressure profile data consists of a number of points connected by straight line segments as illustrated in Figure 4. In order to compute axial loads, shear loads and bending moments, it is necessary to compute the contribution of each of these pressure profile increments to the total load. In computing these incremental loads the point on the increment nearest the base of the fairing is used as a reference point.

First, an equation is derived to represent the shear force contributed by a pressure profile increment at its reference point. Nomenclature for this derivation is illustrated in Figure D1. The expression for ΔC_p as a function of X/D between locations $(X/D)_1$ and $(X/D)_2$ is as follows:

$$\Delta C_p = \Delta C_{P1} - \frac{\Delta C_{P1} - \Delta C_{P2}}{(X/D)_1 - (X/D)_2} [(X/D)_1 - (X/D)] \quad (D1)$$

At a specified location ΔC_p is the difference between the pressure coefficient on the windward side of the fairing and the pressure coefficient at the neutral position on the fairing (see Figure 5). The relationship between the variables in Equation D1 and Figure 4 are as follows:

$$\Delta C_{P1} = CPA(LT+1)$$

$$\Delta C_{P2} = CPA(LT)$$

$$(X/D)_1 = XOD(LT+1)$$

$$(X/D)_2 = XOD(LT)$$

Let

$$A_2 = \frac{\Delta C_{P1} - \Delta C_{P2}}{(X/D)_1 - (X/D)_2} \quad (D2)$$

$$A_1 = \Delta C_{P1} - A_2(X/D)_1 \quad (D3)$$

Then, combining Equations D1, D2 and D3

$$\Delta C_p = A_1 + A_2(X/D) \quad (D4)$$

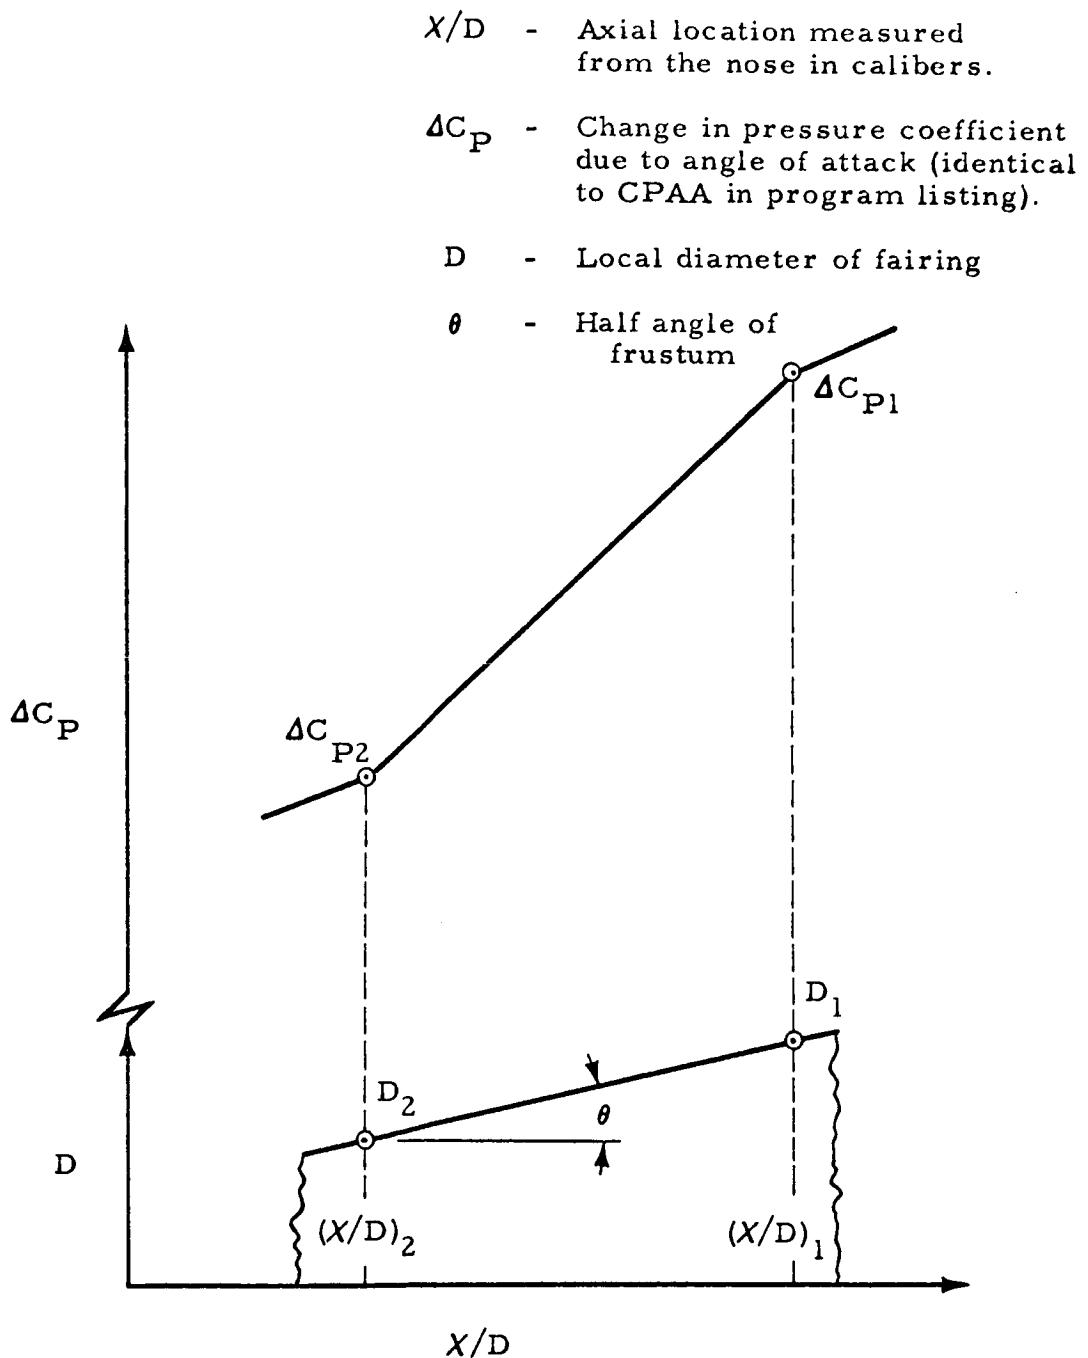

Figure D1 - Nomenclature Used in Derivation of Bending Moment Equation

In a similar manner the following expression can be obtained for the local diameter D .

$$D = A_{D1} + A_{D2}(X/D) \quad (D5)$$

In which

$$A_{D2} = \frac{D_1 - D_2}{(X/D)_1 - (X/D)_2}$$

$$A_{D1} = D_1 - A_{D2}(X/D)_1$$

In Appendix C an equation for the normal force, ΔF_N , for an increment of length, ΔX , was derived for a sinusoidal pressure distribution in the circumferential direction. This equation (Equation C5) is as follows:

$$\Delta F_N = \frac{\pi}{2} D (\Delta X) (\Delta C_P) q$$

in which q is dynamic pressure. Using Equation C5 the running load in the axial direction, w , is expressed as follows:

$$\begin{aligned} w &= \frac{\Delta F_N}{\Delta X} \\ &= \frac{\pi}{2} D (\Delta C_P) q \end{aligned} \quad (D6)$$

By combining Equations D4, D5 and D6, the following expression is obtained for w .

$$w = \frac{\pi}{2} q \left[A_1 A_{D1} + A_1 A_{D2}(X/D) + A_2 A_{D1}(X/D) + A_2 A_{D2}(X/D)^2 \right] \quad (D7)$$

The shear force, v , at any point on the increment is

$$\begin{aligned} v &= \int_{X_1}^X -w dX \\ &= -D_{base} \int_{(X/D)_1}^{X/D} w d(X/D) \end{aligned} \quad (D8)$$

In which D_{base} is the base diameter of the fairing. When the integration is performed, the following expression is the result.

$$v = \frac{\pi}{2} q D_{base} \left\{ \beta_1 \left[\frac{x}{D} - \left(\frac{x}{D} \right)_2 \right] + \beta_2 \left[\left(\frac{x}{D} \right)^2 - \left(\frac{x}{D} \right)_2^2 \right] + \beta_3 \left[\left(\frac{x}{D} \right)^3 - \left(\frac{x}{D} \right)_2^3 \right] \right\} \quad (D9)$$

In which

$$\beta_1 = A_1 A_{D1}$$

$$\beta_2 = \frac{A_1 A_{D2} + A_2 A_{D1}}{2}$$

$$\beta_3 = \frac{A_2 A_{D2}}{3}$$

The incremental shear force, v_i , at the reference point of the i th increment (the point nearest the fairing base), due to aerodynamic pressure acting on the i th increment, is obtained by substituting $(X/D)_1$ for X/D in Equation D9.

The incremental bending moment, M_i , about the reference point of the i th increment is expressed as follows:

$$M_i = \int_{x_2}^{x_1} v dx$$

$$= D_{base} \int_{(X/D)_2}^{(X/D)_1} v d(X/D) \quad (D10)$$

By substituting Equation D9 into Equation D10 and performing the integration, the following expression is obtained.

$$\begin{aligned}
 M_i &= \frac{\pi}{2} q D_{\text{base}}^2 \left\{ \frac{\beta_1}{2} \left[(X/D)_1^2 - (X/D)_2^2 \right] \right. \\
 &\quad - \beta_1 (X/D)_2 \left[(X/D)_1 - (X/D)_2 \right] + \frac{\beta_2}{3} \left[(X/D)_1^3 - (X/D)_2^3 \right] \\
 &\quad - \beta_2 (X/D)_2^2 \left[(X/D)_1 - (X/D)_2 \right] + \frac{\beta_3}{4} \left[(X/D)_1^4 - (X/D)_2^4 \right] \\
 &\quad \left. - \beta_3 (X/D)_2^3 \left[(X/D)_1 - (X/D)_2 \right] \right\} \quad (D11)
 \end{aligned}$$

These incremental shear loads and bending moments are now used to compute the shear load, V_{base} , and bending moment, M_{base} , at the base of the fairing.

$$V_{\text{base}} = \sum_{i=1}^I v_i + \text{Contribution of nose cap} \quad (D12)$$

$$M_{\text{base}} = \sum_{i=1}^I (v_i L_i + m_i) + \text{Contribution of nose cap} \quad (D13)$$

in which I is the total number of increments and L_i is the distance from the base of the fairing to the reference point of the i th increment. The shear moment contribution of the nose cap are discussed below.

As design of the fairing moves from the base toward the nose cap, shear and moment contributed by each of the increments of pressure profile are subtracted from the total shear and bending moment. In moving from the reference point of the $(i-1)$ th increment to the reference point of the i th increment the shear and bending moments at the i th reference point are computed as follows:

$$V_i = V_{i-1} - v_{i-1} \quad (D14)$$

$$M_i = M_{i-1} - m_{i-1} - V_i x_{i-1} \quad (D15)$$

in which x is the length of the increment.

Usually the location of the base of a bay will not coincide with the beginning or end of a pressure profile increment. In this case the pressure profile increment is divided at the base of the bay and each part is treated as a complete increment.

Computation of axial loads is handled in much the same manner as computation of shear force. Using nomenclature similar to that used previously for the ΔC_P calculations (see Figure D1) the equation for the pressure coefficient within a pressure profile increment is

$$C_P = B_1 + B_2 D \quad (D16)$$

in which

$$B_1 = C_{P1} - \frac{C_{P1} - C_{P2}}{D_1 - D_2} D_1 \quad (D17)$$

$$B_2 = \frac{C_{P1} - C_{P2}}{D_1 - D_2} \quad (D18)$$

The incremental axial load is

$$\Delta F_{ax} = \int_{D_1}^{D_2} (q C_P - \Delta P) (\pi D) \frac{dD}{2} \quad (D19)$$

in which ΔP is the difference between fairing internal pressure and ambient pressure. When the expression for C_P is substituted into this equation and the integration is performed, the following equation is obtained.

$$\Delta F_{ax} = \frac{\pi}{2} \left[\frac{1}{2} (q B_1 - \Delta P) (D_1^2 - D_2^2) + \frac{1}{3} q B_2 (D_1^3 - D_2^3) \right] \quad (D20)$$

Total axial load at the base of the fairing is computed by summing up the incremental loads plus the drag contributed by the nose cap. As design of the fairing progresses from the base towards the nose cap, increments of axial load are subtracted in a manner similar to that employed in computing shear loads.

When the bending moment and axial load are known at the base of a bay, the circumferential line load can be computed. This is the load per unit length of circumference parallel to the surface of the skin. The axial load places a uniform compressive load on the circumference. The bending moment places a compressive load on the leeward side and a tensile load on the windward side. The line load due to the axial force is

$$(N\phi)_{AX} = \frac{F_{ax}}{\pi D \cos \theta} \quad (D21)$$

in which

- F_{ax} = Axial force at the base of the bay
- D = Diameter at the base of the bay
- θ = Semi-vertex angle of the bay

Using the assumption that the strain in the skin due to bending is proportional to the distance from the neutral plane, the maximum contribution of bending moment to the line load is computed by the following equation:

$$(N\phi)_{BEND} = \frac{M}{\frac{\pi}{4} D^2} \quad \frac{1}{\cos \theta} \quad (D22)$$

When line load due to bending is superimposed on line load due to axial force the total becomes

$$(N\phi)_{WND} = (N\phi)_{AX} - (N\phi)_{BEND} \quad (D23)$$

$$(N\phi)_{LEE} = (N\phi)_{AX} + (N\phi)_{BEND} \quad (D24)$$

The subscript WND indicates windward side, and the subscript LEE indicates the leeward side.

The contribution of the nose cap to axial load, shear force and bending moment are computed by means of the nose cap drag coefficient, C_D , normal force coefficient per radian angle of attack, $C_{N\alpha}$, and \bar{X} , the distance from the base of the nose cap to center of pressure on the normal plane. The reference area for C_D and $C_{N\alpha}$ is the base area of the nose cap. These parameters can be read into the computer or computed in Subroutine LOAD.

The computations for the nose cap C_D in Subroutine LOAD are based on a computed pressure coefficient at the stagnation point, $(C_P)_{stg}$, and a pressure distribution over the nose cap described by the following equation:

$$C_P = (C_P)_{stg} \sin^2 \phi \quad (D25)$$

in which ϕ is the angle between a plane tangent to the nose cap surface and the line of flight.

In order to compute $(C_P)_{stg}$, the pressure at the stagnation point is assumed to be equal to the stagnation pressure downstream from a normal shock with upstream Mach number equal to that of the vehicle. For one-dimensional flow of a perfect gas with constant specific heat and molecular weight the ratio of downstream stagnation pressure, P_o , to upstream static pressure, P_∞ , is expressed by the following equation taken from Reference 11.

$$\frac{P_o}{P_\infty} = \left[\frac{\gamma+1}{2} M^2 \right]^{\frac{\gamma}{\gamma-1}} \left[\frac{2\gamma}{\gamma+1} M^2 - \frac{\gamma-1}{\gamma+1} \right]^{\frac{1}{1-\gamma}} \quad (D26)$$

in which γ is the specific heat ratio of air and M is the Mach number of the vehicle. When $\gamma = 1.4$, Equation D26 reduces to

$$\frac{P_o}{P_\infty} = \frac{166.92 M^7}{(7M^2 - 1)^{2.5}} \quad (D27)$$

An expression for P_∞ derived from basic definitions is as follows:

$$P_\infty = \frac{q}{\frac{1}{2} \gamma M^2} \quad (D28)$$

For air, Equation D28 reduces to

$$P_\infty = \frac{q}{0.7 M^2} \quad (D29)$$

Using the definition for pressure coefficient

$$(C_P)_{stg} = \frac{P_o - P_\infty}{q}$$

$$= \left(\frac{P_o}{P_\infty} - 1 \right) \frac{P_\infty}{q} \quad (D30)$$

Combining Equations D27, D29 and D30 yields the following equation

$$(C_P)_{stg} = \frac{1}{0.7 M^2} \left[\frac{166.92 M^7}{(7M^2 - 1)^{2.5}} - 1 \right] \quad (D31)$$

The pressure coefficient, C_P , at all points on the nose cap is now defined by Equations D25 and D31. By integrating C_P over the nose cap surface the following expression is obtained for C_D .

$$C_P = \frac{1}{2} (C_P)_{stg} (1 + \sin^2 \theta) \quad (D32)$$

in which θ is the half angle of the top frustum. The axial force contributed by the nose cap is now expressed by the following equation:

$$(\Delta F_{ax})_{CAP} = C_D q A \quad (D33)$$

in which A is the base area of the cap.

For small bluntness ratio (less than 0.2) the bending moment contribution of the nose cap can be approximated by assuming that the nose cap is replaced by a cone having the same half angle as the top frustum. C_{N_a} can then be computed by Equation C14 which is derived in Appendix C.

$$C_{N_a} = 2.03 - 1.2 \theta \quad (D34)$$

Shear force contribution of the nose cap is

$$v_{CAP} = \alpha C_{N_a} q A \quad (D35)$$

For a complete cone the normal force (shear force) acts a point one-third of the distance from the base of the cone to its apex.

$$\bar{x} = \frac{1}{3} \frac{d}{2 \tan \theta} \quad (D36)$$

In which d is the diameter of the nose cap base. The bending moment at the base of the nose cap is expressed as follows:

$$m_{CAP} = \bar{x} v_{CAP} \quad (D37)$$

APPENDIX E
LATERAL PRESSURE

The lateral pressure used to design the fairing is the difference between internal and external surface pressure multiplied by a factor of safety. This pressure is computed on both the windward and leeward sides of the bay, using the pressure profile data and input aerodynamic data.

Pressure coefficients on the windward and leeward sides of the bay are expressed by the following equations.

$$(C_P)_{WND} = C_{PO} + \Delta C_P \quad (E1)$$

$$(C_P)_{LEE} = C_{PO} - \Delta C_P \quad (E2)$$

In which

$(C_P)_{WND}$ = pressure coefficient on windward side

$(C_P)_{LEE}$ = pressure coefficient on leeward side

C_{PO} = pressure coefficient at zero angle of attack

ΔC_P = change in pressure coefficient due to angle of attack

The difference between surface pressure and free-stream pressure is expressed by the following equations.

$$(P_S)_{WND} - P_\infty = (C_P)_{WND} q \quad (E3)$$

$$(P_S)_{LEE} - P_\infty = (C_P)_{LEE} q \quad (E4)$$

In which

P_S = surface pressure

P_∞ = free-stream pressure

q = dynamic pressure

Recall that the difference between internal pressure and free-stream pressure is an input parameter.

$$\Delta P = P_{int} - P_\infty \quad (E5)$$

In which

ΔP = the input value of pressure difference

P_{int} = absolute pressure inside the fairing

Combining Equation E3 with E5 and E4 with E5 the following equations for pressure difference are obtained.

$$(P_S)_{WND} - P_{int} = (C_P)_{WND} q - \Delta P \quad (E6)$$

$$(P_S)_{LEE} - P_{int} = (C_P)_{LEE} q - \Delta P \quad (E7)$$

Design pressures are obtained by multiplying these pressure differences by the factor of safety, FS.

$$(P_{des})_{WND} = FS \left[(C_P)_{WND} q - \Delta P \right] \quad (E8)$$

$$(P_{des})_{LEE} = FS \left[(C_P)_{LEE} q - \Delta P \right] \quad (E9)$$

APPENDIX F

SHELL DESIGN

When bay geometry, bay loading and shell thickness are specified the adequacy of the shell design is determined in Subroutine CHKL0D. In analyzing a bay design both line load (from Subroutine LOAD) and design pressure (from Subroutine PRESUR) are considered on both the windward and leeward sides of the fairing. An interaction relationship is used to account for the combined effect of these two types of loading.

The following interaction equation, which is used in Subroutine CHKL0D, was developed by Paul Seide (Reference 12).

$$(R_p)_{al} = \left[\sqrt{1 + \left(\frac{R_{AX}}{\sqrt{3}} \right)^2} - 2 \left(\frac{R_{AX}}{\sqrt{3}} \right) \right] x \\ \sqrt{\sqrt{1 + \left(\frac{R_{AX}}{\sqrt{3}} \right)^2} + \left(\frac{R_{AX}}{\sqrt{3}} \right)} \quad (F1)$$

In which

$$R_p = \frac{P}{P_{crt}} \quad (F2)$$

$(R_p)_{al}$ = maximum allowable value for R_p

$$R_{AX} = \frac{N_\phi}{(N_\phi)_{crt}} \quad (F3)$$

P = design pressure

P_{crt} = the external to internal pressure difference at which the shell would fail in the absence of other forms of loading (critical pressure)

N_ϕ = circumferential line load

$(N_\phi)_{crt}$ = the compressive circumferential line load at which the shell will buckle in the absence of other loading (critical line load)

Critical pressure for the shell is computed by the method presented in Section 6.23.2, Reference 4. This is the "equivalent cylinder" technique of Reference 13 applied to the elastic design of truncated cones with a taper

ratio $(1 - R_1/R_2) \leq 0.95$ and a semivertex angle $\theta \leq 75$ deg:

$$P_{cr} = \frac{C_P \pi^2 E}{12 Z \sqrt{1 - \mu^2}} \left(\frac{t}{\rho} \right)^2 \quad (F4)$$

where

$$C_P = \frac{0.875 Z + 1.122 \sqrt{Z}}{4.385 + \sqrt{Z}} \quad (F5)$$

$$Z = \frac{\sqrt{1 - \mu^2}}{\eta_r} \left(\frac{L}{R_2} \right)^2 \left(\frac{R_2}{t} \right) \frac{1}{\cos \theta} \quad (F6)$$

$$\eta_r = 0.60 (0.70 + R_1/R_2) \quad (F7)$$

$$\left(\frac{\rho}{t} \right) = \frac{\eta_r}{\cos \theta} \left(\frac{R_2}{t} \right) \quad (F8)$$

and

E = modulus of elasticity

μ = Poisson's ratio

L = length of shell

t = thickness of shell

θ = semivertex angle of frustum

ρ = an equivalent radius

R_1 = small diameter of frustum

R_2 = large diameter of frustum

(For computational convenience the form of the above equations has been altered in the design program.)

The critical line load is computed by equations for short monocoque cylinders (Section 6.11.2 of Reference 4) modified by E. Hendrix, Reference 14, for use in the analysis of conical frustums. The basic equation is

$$F_{crt} = C \frac{\eta E}{(\rho/t)} \quad (F9)$$

In which

F_{crt} = the critical compressive stress

C = the buckling coefficient

E = modulus of elasticity

η = plasticity reduction factor

The ratio, ρ/t , is computed by Equations F7 and F8 above.

The buckling coefficient, C , is expressed by the following equation:

$$C = \frac{0.871}{\left(\frac{\rho}{t}\right)^{m-1} \left(\frac{L}{\rho}\right)^n} \quad (F10)$$

In which

$$n = 2(m-1)$$

Values for m are presented graphically in Figure 6.11-2 of Reference 4 for three different levels of probability -- average, 90% and 99%. A curve-fit of the 99% probability curve yielded the following equation which is used in the design program.

$$m = -0.378 \left[\ln \left(\frac{\rho}{t} \right) \right]^2 + 0.3 \left[\ln \left(\frac{\rho}{t} \right) \right] + 0.792 \quad (F11)$$

The parameter η in Equation F9 is a plasticity reduction factor which is equal to one for the low loading intensities typical of nose fairings.

Since loads are expressed in terms of line load it is necessary to convert the critical compressive stress to the critical compressive line load. This is done by the following equation

$$(N_\phi)_{crt} = (F_{crt})(t) \quad (F12)$$

The ratios indicated in Equations F2 and F3 can now be calculated, and a value for $(R_P)_{al}$ can be computed by Equation F1. If R_P is equal to or less than $(R_P)_{al}$ the design is satisfactory.

For use in the program it is desirable to define a new parameter, C_K , which is equal to or less than 1 for a satisfactory design. Algebraically, C_K , R_P and $(R_P)_{al}$ are related as follows:

$$C_K = 1 + R_P - (R_P)_{al} \quad (F13)$$

C_K is computed for both the windward and leeward sides of the fairing, corresponding to the variable names CHKWND and CHKLEE in the computer program. When both CHKWND and CHKLEE are equal to or less than one the design is adequate. In the computer output under "Design Details of Conical Frustums" some of the ratios and parameters developed in this appendix are listed for both the windward and leeward sides of the bay under the following headings:

N_ϕ - Line Load

R_{ax} - Stress Ratio, Axial

R_P - Stress Ratio, Press.

C_K - Load Index

APPENDIX G
STIFFENING RING DESIGN

After the shell portion of a bay has been designed, it is necessary to provide a ring of adequate stiffness to prevent general instability of the composite structure, i.e., to prevent the entire side of the fairing from caving in. This ring is placed at the upper end of the bay. For tapered conical sections, lateral crushing pressure is normally the dominant factor in ring size determination. For these sections, the required moment of inertia of such a ring is expressed by the following equation which was used by Nevins and Helton in a similar study reported in Reference 1.

$$I_{\text{req}} = L_{\text{bay}} \left(\frac{D}{2 \cos \theta} \right)^2 \left(\frac{1}{t} \right)^{1/3} \left[\frac{(P_{\text{des}})_{\text{WND}} D_b}{11.02 E \tan \theta} \right]^{4/3} \quad (\text{G1})$$

in which

- L_{bay} = length of bay, in.
- D = small diameter of bay, in.
- θ = semivertex angle of bay
- t = skin thickness, in.
- $(P_{\text{des}})_{\text{WND}}$ = the crushing pressure on the windward side of the fairing, psi.
- D_b = the base diameter of the fairing, in.
- E = modulus of elasticity of the material, psi.

This equation is a modification of the general stability equation developed by Becker in Reference 5.

For cylindrical sections, axial loads are higher and lateral collapse pressure much lower than in conical sections, hence rings are sized on a different basis. As stated in Section 1.13, the cylindrical section is divided into bays of equal length using stiffening rings of identical cross-section. Skin gauge for the first bay is determined by the same methods used elsewhere in the fairing. Then assuming that the skin gauge and loading determined for the first bay prevail throughout the cylindrical section, the minimum ring cross-section required to prevent general instability is computed by the method of Baruch-Singer adapted for use in this program by A. B. Burns (see Appendix K).

After computing the moment of inertia required of the ring, the ring cross-section which will provide this moment of inertia is selected. The three types of cross-sectional shapes which may be specified are shown in Figure 3. Also to be specified are B/t ratios of the web(s) and flanges. When designing the ring, the computer program selects the smallest standard skin gauge which provides a ring cross-section with moment of inertia equal to or greater than that required, providing that the selected ring has no buckled flanges.

It is necessary to check for flange (or web) buckling because large B/t values may be input, and these large B/t values present a definite possibility of local instability occurring. In making this check, a small (one percent) ovality tolerance was assumed, and bending stress due to this ovality effect are added to the hoop compression stress. The total flange stress thus obtained, is compared to an input flange buckling stress level (FCFB), and if excessive, the ring web thickness is increased as required.

APPENDIX H

STRUCTURAL DESIGN OF SPHERICAL NOSE CAP

The nose cap design is analyzed structurally as an unstiffened, non-shallow spherical cap with uniform shell thickness. The method of analysis used is presented in Section 6.23.1 of Reference 4. From experiments it is observed that non-shallow (the ratio of height to radius is greater than 1/6) spherical caps buckle in the form of a small dimple in some area of the surface of the cap. Therefore, the critical buckling pressure for non-shallow caps is independent of the height to radius ratio, depending only on the radius to thickness ratio and the modulus of elasticity of the shell material.

The equation recommended in Reference 4 is

$$P_{crt} = \frac{0.606 E}{\left(\frac{R}{t}\right)^2 e^{0.04 \sqrt{R/t}}} \quad (H1)$$

In which

P_{crt} = critical buckling pressure

R = nose cap radius

E = modulus of elasticity

t = shell thickness

A trial and error procedure is used in determining the minimum shell thickness required for the nose cap. When R , E and design pressure are known the shell thickness is increased by 0.001 inch increments until P_{crt} is equal to or greater than the design pressure computed for the nose cap.

Maximum design pressure for the nose cap occurs at the stagnation point. Assuming that the pressure on this point is the same as the stagnation pressure downstream from a normal shock, the pressure coefficient, $(C_p)_{stg}$, is expressed by Equation D30, and the design pressure is expressed by the following equation:

$$(P_d)_{CAP} = (FS) \left[q (C_p)_{stg} - \Delta P \right] \quad (H2)$$

in which

FS = factor of safety

q = dynamic pressure

ΔP = internal to free-stream pressure difference

APPENDIX I

DERIVATION OF APPROXIMATE BAY LENGTH EQUATIONS

Because of the complexity of the equations relating bay geometry and acceptable loading level it is necessary to determine bay length by an iterative procedure. Computer time can be saved by making a good first guess for this bay length. After establishing the bay length for the first of seven skin gauges to be used in the search for the optimum configuration, the lengths corresponding to each of the remaining six skin gauges can be scaled by using the ratio of the skin gauges and the previous bay length, both of which are known. Because lateral pressure is the dominant type of loading the derivation of the scaling equation which follows is based on the equation in Appendix F relating critical buckling pressure and bay geometry.

These equations are as follows:

$$P_{CR} = \frac{C_P \pi^2 E}{12 Z \sqrt{1 - \mu^2}} \quad \frac{1}{(\rho/t)^2} \quad (I1)$$

$$C_P = \frac{0.875Z + 1.122\sqrt{Z}}{4.385 + \sqrt{Z}} \quad (I2)$$

$$Z = \frac{\sqrt{1 - \mu^2}}{\eta_R \cos \theta} \quad \left(\frac{2L}{D_B} \right)^2 \quad \left(\frac{D_B}{2t} \right) \quad (I3)$$

$$\eta_R \approx 0.6 \left(0.7 + \frac{D}{D_B} \right) \quad (I4)$$

$$\frac{\rho}{t} = \frac{\eta_R}{\cos \theta} \quad \left(\frac{D_B}{2t} \right) \quad (I5)$$

In which

- P_{cr} = lateral pressure at which the skin buckles
- E = modulus of elasticity
- μ = Poisson's ratio
- θ = half angle of bay
- L = bay length
- D = small diameter of bay
- D_B = large diameter of bay
- t = skin thickness
- ρ = an effective bay radius

In equation I1 the only parameters influenced by bay length and skin gauge are C_P , Z and ρ/t . Therefore, the following relationship can be written, using subscript 1 to indicate the parameters associated with the bay which has been designed and subscript 2 to indicate parameters associated with the bay whose length is being estimated.

$$\frac{(C_P)_2}{(C_P)_1} = \frac{Z_1}{Z_2} \left[\frac{(\rho/t)_1}{(\rho/t)_2} \right]^2 = 1 \quad (I6)$$

A log - log plot of C_P versus Z using Equation I2 reveals that Equation I2 can be replaced by the following approximate relationship.

$$C_P = 0.37Z^{0.64} \quad (I7)$$

From which

$$\frac{(C_P)_2}{(C_P)_1} = \left(\frac{Z_2}{Z_1} \right)^{0.64} \quad (I8)$$

Substituting into Equation I6

$$\left(\frac{Z_1}{Z_2} \right)^{0.36} \left[\frac{(\rho/t)_1}{(\rho/t)_2} \right]^2 = 1 \quad (I9)$$

Again dropping terms not influenced by L and t, the following ratio is obtained from Equation I3.

$$\frac{Z_1}{Z_2} = \left(\frac{n_{R2}}{n_{R1}} \right) \left(\frac{L_1}{L_2} \right)^2 \frac{t_2}{t_1} \quad (I10)$$

And from Equation I4

$$\frac{n_{R1}}{n_{R2}} = \frac{0.7 + D_1/D_B}{0.7 + D_2/D_B} \quad (I11)$$

Which can be written as follows using the trigonometric relationship between D , D_B , and θ .

$$\frac{n_{R1}}{n_{R2}} = \frac{1.7 - 2 \frac{L_1}{D_B} \tan\theta}{1.7 - 2 \frac{L_2}{D_B} \tan\theta} \quad (I12)$$

From Equation I5

$$\frac{(\rho/t)_1}{(\rho/t)_2} = \left(\frac{n_{R1}}{n_{R2}} \right) \left(\frac{t_2}{t_1} \right) \quad (I13)$$

By substituting Equation I10 and I13 into Equation I9 the following relationship is obtained.

$$\frac{L_2}{L_1} = \left(\frac{n_{R1}}{n_{R2}} \right)^{2.28} \left(\frac{t_2}{t_1} \right)^{3.28} \quad (I14)$$

However, it is necessary to have a value for L_2 before computing the ratio n_{R1}/n_{R2} using Equation I12. A close approximation to L_2 can be obtained by letting n_{R1}/n_{R2} be equal to 1 in Equation I14. The ratio n_{R1}/n_{R2} can then be computed using Equation I12, and the ratio L_2/L_1 , can be obtained from Equation I14.

APPENDIX J

THERMAL ANALYSIS

The maximum temperature reached by the skin due to aerodynamic heating can be controlled by placing a lower limit on the thickness of skin to be used in critical locations. Provisions have been made in the program to place such constraints on both the nose cap and top frustum of the fairing, either by specifying the minimum skin thickness to be used or by specifying the maximum temperature to be reached by the skin.

Design curves for determining the minimum thicknesses have been prepared by LMSC/HREC. These curves and the methods used in generating the data for these curves are presented in Reference 6. The trajectory used in this analysis was a nominal two-stage Saturn V ascent trajectory to a 100 nautical mile circular orbit.

Both laminar and turbulent heating occur during the flight. Laminar flow was assumed to exist when the Reynolds number based on momentum thickness of the local boundary layer was equal to or less than 500. Turbulent flow was assumed to exist at Reynolds numbers above 500. When the flow was laminar, the method of Fay and Riddell (Reference 7) was used together with the laminar heating rate distribution of Lees (Reference 8). When the flow was turbulent, heating rates were calculated by using a method from Reference 9 (Bromberg, Fox and Ackermann). Radiation from the outer surface was also taken into account.

Other assumptions were that the heat flow is one-dimensional, that at any time or location on the fairing the skin temperature is uniform throughout the thickness of the skin, and that the inner surface of the skin is perfectly insulated. These latter assumptions were found to have only a minor effect on the final results.

Maximum temperature constraints are applied to the nose cap and the top frustum. The thickness of material required to limit the maximum temperature of the nose cap is based on heating at the stagnation point of the nose cap, and the thickness required for the top frustum is based on heating on the nose cap at its junction with the top frustum. Thus, the heating data required to establish these constraints can be obtained from a spherical shell.

Several hundred data points were generated for each of the following five materials: aluminum, magnesium, titanium, stainless steel and Lockalloy. Each data point for a specified material is completely described by the following four parameters:

- R = radius of spherical nose cap
- θ = the angle between the line of flight and a plane tangent to the nose cap at the point of interest

T_{max} = the maximum temperature reached by the skin, $^{\circ}\text{F}$

t = thickness of the skin

When applying this data to nose fairing design, θ is equal to 90° at the stagnation point and to the half angle of the top frustum at the junction of the nose cap and top frustum. (Note that ϕ in Reference 6 is the complement of θ .)

In order to avoid the necessity of storing all of these data points in the fairing design program, a set of linear algebraic equations which fit the data within a few percent was developed by a technique commonly referred to as multiple regression analysis. A detailed description of multiple regression analysis can be found in many statistical text books such as Reference 10, Chapters 4 and 5.

Two major steps are involved in such an analysis. First, it is necessary to establish the form of the equation relating the variables which describe the data points. This step can be based on intuition and/or a knowledge of the physical laws relating the variables. This equation must be reduced to linear form, which is then referred to as a linear model. The linear model has the general form

$$y = c_1 x_1 + c_2 x_2 + \dots + c_n x_n \quad (\text{J1})$$

The variables y and x_1, x_2, \dots, x_n may be grouped parameters such as $(T_{max} - 70)$ and T_{max} / \sqrt{R} . However, these variables must be such that numerical values can be obtained for each variable for each data point.

Having developed a linear model the next step is to determine the set of coefficients (c_1, c_2, \dots, c_n) which give the best fit to the data. This is done by means of the "least squares" curve fit technique. Usually several different linear models are tried in an attempt to curve-fit a given set of data.

For this application two models were developed, one for the stagnation point and the other for the point of tangency between the spherical nose cap and the top frustum. A set of coefficients was computed for each of the two models for each of the five materials, making a total of ten sets of coefficients. The equations and coefficients appear in Subroutine THERML.

The linear model representing heating at the stagnation point is based on laminar and radiative heating theory. It is postulated that the following

relationship is approximately true.

$$\rho C_P t (T_{max} - 70) = K_1 + \frac{K_2}{\sqrt{R}} (K_3 - T_{max}) - K_4 \epsilon (T_{max} + 460)^4 \quad (J2)$$

in which

ρ = density of skin

C_P = specific heat of skin

ϵ = emissivity of skin

The terms in Equation J2 represent the following physical quantities:

$C_P t (T_{max} - 70)$ = the maximum quantity of heat stored in a unit area of skin during the flight

K_1 = a constant

$\frac{K_2}{\sqrt{R}} (K_3 - T_{max})$ = convective heat input (laminar flow) to the unit area

$K_4 \epsilon (T_{max} + 460)^4$ = radiative heat loss from the unit area

When material properties are dropped (coefficients are determined for each material) and when the multiplications are performed Equation J2 reduces to the following linear form.

$$t (T_{max} - 70) = a_1 + a_2 \frac{1}{\sqrt{R}} + a_3 \frac{T_{max}}{\sqrt{R}} + a_4 (T_{max} + 460)^4 \quad (J3)$$

Comparing this to Equation J1

$$y = t (T_{max} - 70)$$

$$x_1 = 1$$

$$x_2 = \frac{1}{\sqrt{R}}$$

$$x_3 = \frac{T_{max}}{\sqrt{R}}$$

$$x_4 = (T_{max} + 460)^4$$

Using the data generated in Reference 6 the coefficients a_1 , a_2 , a_3 and a_4 can be determined by the least-squares technique.

A more complex model is required to represent heating at the point at which the nose cap is tangent to the top frustum. Turbulent flow occurs during part of the flight, and laminar flow occurs during the remainder. It is also necessary to specify the angular location, θ , on the sphere. The following model was postulated:

$$\rho C_P t (T_{max} - 70) = K_1 + \frac{K_2}{\sqrt{R}} (K_4 + \sin^2 \theta) (K_5 - T_{max}) \\ + \frac{K_3}{R^{0.2}} (K_4 + \sin^2 \theta) (K_5 - T_{max}) - K_6 \epsilon (T_{max} + 460)^4$$

The additional terms in this equation have the following physical significance:

$$\frac{K_2}{\sqrt{R}} (K_4 + \sin^2 \theta) (K_5 - T_{max}) = \text{convective heat input during laminar flow}$$

$$\frac{K_3}{R^{0.2}} (K_4 + \sin^2 \theta) (K_5 - T_{max}) = \text{convective heat input during turbulent flow}$$

in which $(K_4 + \sin^2 \theta)$ accounts for pressure variation with angular position on the nose cap. When material properties are dropped and the multiplications are performed the quantities corresponding to the variables in the linear model are as follows:

$$y = t (T_{max} - 70)$$

$$x_1 = 1$$

$$x_2 = \frac{1}{\sqrt{R}}$$

$$x_3 = \frac{T_{\max}}{\sqrt{R}}$$

$$x_4 = (T_{\max} + 460)^4$$

$$x_5 = \frac{\sin^2 \theta}{\sqrt{R}}$$

$$x_6 = \frac{T_{\max} \sin^2 \theta}{\sqrt{R}}$$

$$x_7 = \frac{1}{R^{0.2}}$$

$$x_8 = \frac{T_{\max}}{R^{0.2}}$$

$$x_9 = \frac{\sin^2 \theta}{R^{0.2}}$$

$$x_{10} = \frac{T_{\max} \sin^2 \theta}{R^{0.2}}$$

Note that y and x_1, x_2, x_3 , and x_4 are identical for both the stagnation point and tangency point models.

Coefficients were determined for each of the five materials at both the stagnation point and the tangency point. A summary of pertinent information about the curve fit is presented in Table J1.

The coefficients stored in Subroutine THERML were determined for a nominal two-stage Saturn V ascent trajectory to a 100 nautical mile orbit. If the subroutine is to be used for trajectories which differ greatly from this trajectory it would be adviseable to determine a new set of coefficients based on thermal data for the new trajectory. The linear models used in Subroutine THERML will probably be valid for a wide range of trajectories.

TABLE J1
THERMAL CURVE-FIT INFORMATION

Location	Material	Range of Data				No. of Data Points	Range of Errors in Skin Thickness, Percent		
		Temperature, °F		Skin Thickness, in			Negative	Positive	
		Low	High	Low	High				
Stagnation Point	Aluminum	366	987	0.050	0.400	28	-0.66	0.50	
	Magnesium	388	1000	0.060	0.500	28	-0.93	0.42	
	Titanium	579	1234	0.040	0.250	21	-0.39	0.30	
	Stainless Steel	746	1361	0.025	0.080	23	-0.91	1.26	
	Lockalloy	369	1175	0.035	0.300	30	-1.50	0.78	
Tangency Point	Aluminum	404	1091	0.025	0.200	124	-3.44	3.84	
	Magnesium	396	1132	0.020	0.300	149	-7.00	4.81	
	Titanium	475	1365	0.015	0.200	125	-3.49	3.79	
	Stainless Steel	647	1147	0.0125	0.060	72	-4.55	7.84	
	Lockalloy	395	1234	0.025	0.150	105	-6.03	7.20	

NOTES:

Nose cap radius ranges from 13 to 52 inches for both locations and all materials.

Angular location of the tangency point (half angle of the top frustum) ranges from 0 to 45 degrees for all materials for the tangency point data.

THE BARUCH-SINGER GENERAL
INSTABILITY ANALYSIS

by

A. B. Burns, member
Solid Mechanics Laboratory
LMSC Research Laboratories

THE BARUCH-SINGER GENERAL
INSTABILITY ANALYSIS

Analytical Basis

The equations presented by Baruch and Singer (Ref. 1) may be easily modified to predict the classical buckling load for the general mode of instability in stiffened cylinders subjected to a combination of axial compression and either internal or external lateral pressure. In the present analysis, modified Baruch-Singer equations have been written in a form which yields the classical axial load-carrying ability of the cylinder given a particular ring geometry and spacing, and a specified lateral pressure. These equations have two significant features: (1) they include the effects of ring eccentricity, and (2) they assume that local instability does not precede the onset of general instability in any of the elements of the composite cross-section. In addition, they apply to cylinders stiffened with equally spaced rings of identical cross section.

Of course, the classical buckling load is usually much too optimistic for cylinders carrying predominantly axial loads, and a practical method for adjusting the classical buckling downward is required. The method utilized here is that recommended in Ref. 2. Briefly, the critical buckling load is equal to the minimum postbuckling load (the lower bound), plus a percentage of the difference between the classical buckling load (the upper bound) and the minimum postbuckling load, depending upon the geometry of the cylinder. Thus:

$$\left(\frac{N_x}{RE}\right)_{cr} = \frac{N_{cl}}{RE} \left[\frac{N_{min}}{\frac{N_{cl}}{c\ell}} + c(1 - \frac{N_{min}}{\frac{N_{cl}}{c\ell}}) \right]$$

When $N_{\min} = N_{cl}$, i.e., when the upper and lower bounds to the critical buckling load are equal, the critical buckling load is set equal to the classical buckling load and the term containing the factor c is zero.

When $N_{\min} < N_{cl}$, the factor c has the form:

$$c = (\varphi - 0.12)/0.88$$

where φ , an empirical reduction factor, is defined as follows:

$$\varphi = 1.0 \text{ when } (R/t)_e \leq 33 .$$

$$\varphi = 6.48(R/t)_e^{-0.54} \text{ when } (R/t)_e > 33 .$$

where:

$$(R/t)_e = R/t (t_x/t)^{0.5} [5.46(I_x/t^3 + I_y/t^3)]^{-0.5}$$

Note that the formulation for $(R/t)_e$ reduces to R/t for monocoque cylinders. Thus, the reduction factor is tailored to apply to stiffened cylinders ranging from those with minimal stiffening to those with extensive stiffening.

Although the classical buckling load calculated here is dependent upon the applied lateral pressure, the minimum postbuckling load is calculated assuming zero pressure. This procedure has been adopted in the interest of expediency because a major effort beyond the intent of this study would be required to obtain minimum postbuckling loads which represent the combination of axial compression and lateral pressure loads on the cylinder. Likewise, the correction factor c is also calculated assuming zero pressure since it is expected that axial compression will be the predominant loading on cylinders analyzed with this subroutine. Under these circumstances, these limitations are expected to result in minor conservatism.

Computer Solution

The subroutine which has been written to solve the above noted equations accepts data relative to the rings in a general form; ring area, ring moment of inertia, ring centroidal distance, ring spacing and ring torsional stiffness are required. Therefore, any ring cross-section may be subjected to analysis in this subroutine for which the above noted properties have been written in a common form and are made available elsewhere in the program.

The classical buckling load is obtained by setting $m = 1$ and systematically investigating increasing values of n until a minimum N_{cl} is obtained. The value of m is then increased and n is again varied. If $N_{cl_{m=1}} \leq N_{cl_{m>1}}$, the cylinder is short; that is, the natural axial half wave length is greater than the length of the cylinder, and $N_{cl_{m=1}}$ is accepted as the classical buckling load. If $N_{cl_{m=1}} > N_{cl_{m>1}}$, the cylinder is long, and the value of m is increased in increments (and for each increment, the value of n is varied) until the lowest value of N_{cl} is found. As part of these calculations, an effective width factor Y is applied to the skin between rings, as required, to account for shear lag effects which reduce the bending stiffness of the composite section in the circumferential direction. Note that the skin is still assumed to be non-buckling. The minimum postbuckling load is subsequently calculated. Information pertinent to this quantity is stored as constant data in the program. This information has been taken from the work of Almroth (Ref. 3) wherein Almroth's graphical results have been converted here into tabular form. Additional subroutines are used to interpolate between adjacent points in the constant data. Initial calculations for the minimum postbuckling load establish whether the cylinder is long or short, and are carried out in a manner similar to that described above relative to the classical buckling

load. If the cylinder is long, either subroutine TERP 4 or TERP 5 is called for interpolation purposes, depending upon the value of the geometric parameter γ . If the cylinder is short, subroutine TERP 7 is called.

Having calculated the classical buckling load and the minimum postbuckling load, the correction factor c is calculated as outlined above and these quantities are then used to calculate the critical buckling load.

The pressure applied to the cylinder may be positive (collapse pressure) or negative (burst pressure). For positive pressures, the subroutine may yield negative critical buckling loads in the early stages of sizing the rings, which indicate that the shell geometry is critical under the applied pressure, and tensile axial loads are required to maintain stability. Positive critical buckling loads (compression) will be obtained as the rings are increased in size.

The subroutine computes an elastic critical buckling load. Corrections for plasticity (or maximum permissible stress) are made elsewhere. Although the present subroutine has been written for internally stiffened cylinders, cylinders stiffened externally with rings may also be analyzed, if desired, by setting the control IRECC appearing at the beginning of the subroutine equal to -1.

Notation

c	correction factor
E	Young's Modulus
I_x	moment of inertia per unit of circumferential width of cylinder wall cross section, taken about the centroid of the cross section.
I_y	moment of inertia per unit of length of cylinder wall cross section, taken about the centroid of the cross section
m	number of axial half-waves
n	number of circumferential full waves
N_{cl}	classical buckling load per unit of circumference for the general instability mode
N_{min}	minimum postbuckling load per unit of circumference for the general instability mode
N_x	applied axial load per unit of circumference
p	applied pressure per unit of surface area
R	cylinder radius
t	cylinder wall thickness
t_x	equivalent thickness in the axial direction (see Ref. 2)
t_y	equivalent thickness in the circumferential direction (see Ref. 2)
γ	effective width correction factor (see Ref. 2)
γ	$I_x t_y / I_y t_x$
φ	empirical correction factor

Subroutine Symbols

AIST	ring moment of inertia
AST	ring area
CR	critical buckling line load (pounds/in)
D	ring centroidal distance
DY	ring spacing
E	Young's Modulus
P	collapse pressure (psi); burst pressure if entered as negative quantity.
R	cylinder radius
T	cylinder wall gage
TK	ring torsion constant
XL	cylinder length
XMU	Poisson's ratio
