REPORT NO. 2286-950002 JUNE 26, 1966

(PREPARED UNDER CONTRACT NO. NAS8-11215)

GEORGE C MARSHALL SPACE FLIGHT CENTER
NATIONAL AERONAUTICS AND SPACE ADMINISTRATION
HUNTSVILLE, ALABAMA 35812

BELL AEROSYSTEMS -A TEXTON COMPANY

#### **FOREWORD**

This report was prepared by Bell Aerosystems Company under NASA Contract NAS8-11215 and covers work performed during the period 1 May 1965 to 31 May 1966. The contract was administered under the direction of Mr. Jerrell M. Thomas, Contracting Officers Representative, and Mr. George Tovar, Alternate, Contracting Officers Representative, at NASA, George C. Marshall Space Flight Center.

The authors wish to acknowledge the assistance and contributions of the following personnel: W. A. Luberacki, D. M. Dupree, R. G. Dworak, Y. M. Echenoz, R. A. Van Slooten and J. F. Bolton.

Most of the numerical results presented in this report were obtained with the computer facilities at the George C. Marshall Space Flight Center Huntsville, Alabama in close cooperation with J. Thomas and G. Tovar.

#### **ABSTRACT**

Axially symmetric dynamic response solutions for infinite and finite length cylinders subjected to pressure transients which arise in propulsion systems are presented in Volume I. Pressure transient types considered in detail are of the spike, step, ramp and sinusoidal forms. Solutions for simple-simple and fixed-fixed boundary conditions are given and used as the basis for design charts which yield maximum stresses. A discussion of advanced problems is included.

Volume II is a User's Manual for a General Purpose Digital Computer Program capable of predicting the dynamic response of cylinders subjected to ramp and sinusoidal pressure transients. The dynamic response for many traverses of a pressure transient from one end of the cylinder to the other can be computed by the program for the case where one end of the cylinder is closed (by a valve) and the other end attached to a relatively large container.

## **SYMBOLS**

c = <u>Viscous</u> damping coefficient

$$c_{CR} = \sqrt{\frac{\rho E}{g}} \frac{h}{R}$$
, critical damping coefficient for  $n = 1$ 

$$D = \frac{E h^3}{12 (1 - \nu^2)}$$

e = half wave length of sinusoidal pressure transient

E = Young's modulus

F = nondimensional function of time

h = cylinder wall thickness

k = wave number

 $k_n = eigenvalue$ 

 $K_n = k_n \ell$ 

length of cylinder

 $m = \frac{\rho_h}{g}$ 

M = axial bending moment per unit of circumferential length

$$\mathbf{M}_{0}^{\mathbf{X}} = \frac{\mathbf{pRh}}{\sqrt{12 (1-\nu^{2})}}$$

$$M_{op} = \frac{Ph^{1/2}R^{1/2}}{4\sqrt{12(1-\nu^2)}}$$

M<sub>d</sub> = hoop bending moment per unit axial length

 $\overline{\mathbf{M}}_{\mathbf{M}}$  = nondimensional axial bending moment per unit of circumferential length

n = subscript, indicates mode number

N = number of terms taken in series solution

N<sub>A</sub> = hoop membrane force per unit length

 $N_{v}$  = axial membrane force per unit length

p = maximum intensity of radial pressure load

P = ring line load per unit of circumferential length

 $\overline{q}$  = normal force intensity

q = intensity of radial pressure load

Q = shear force per unit length

Q = Fourier load transform

R = mean cylinder radius

t = time

t = valve closure time

 $t_0 = \frac{l}{v}$ 

 $T_n$  = function of time

u = axial displacement component

v = speed of transient pressure

v<sub>G</sub> = group velocity

w = radial displacement component of cylinder

 $W_n(\overline{\xi}) = eigenfunction$ 

 $W(\alpha) = Fourier deflection transform$ 

$$w_0 = \frac{p R^2}{E h}$$

$$w_{o_{P}} = \frac{P\sqrt[4]{12(1-\nu^{2})}}{E} \left(\frac{R}{h}\right)^{3/2}$$

 $\overline{\overline{\mathbf{w}}}$  = nondimensional radial displacement of cylinder

x = axial coordinate of cylinder

 $\alpha = c \frac{R}{h} \sqrt{\frac{q}{\rho E}}$ , nondimensional damping parameter

$$\frac{\overline{\alpha}}{\alpha} = \alpha \sqrt{\frac{\beta}{2\lambda}}$$

$$\beta = \frac{\int_{\mathbb{R}^2} 2}{\mathbb{R}^2} \sqrt{12 (1-\nu^2)}$$
, length parameter

$$\gamma = 4\sqrt{\frac{Eh}{R^2D}}$$

 $\Gamma$  = frequency

$$\epsilon = \frac{e}{\int$$

 $\epsilon_{y} =$ axial strain

 $\epsilon_{\phi}$  = circumferential strain

 $\frac{\rho \text{ v}^2}{2 \text{ Eg}} = \frac{R}{h} \sqrt{12 (1-\nu^2)}$ , speed parameter

Poisson's ratio

 $\gamma$  (x-vt), dimensionless moving coordinate, infinite shell

weight density

phase velocity

 $\frac{x}{1}$ , dimensionless axial coordinate, finite shell

stress in axial direction

stress in circumferential direction

 $\frac{t}{t}$  , nondimensional time

 $\frac{\mathbf{t}}{\mathbf{c}} = \text{nondimensional valve closure time}$ 

natural frequency

**ω** = damped natural frequency

nondimensional natural frequency

nondimensional damped natural frequency

Additional symbols are defined in the text where they occur.

#### I. INTRODUCTION

During the various phases of operation of the propulsion systems of space vehicles, severe pressure transients are experienced by the component cylindrical ducts. This report presents the results of a study of the dynamic response of circular cylinders subjected to pressure transient forms commonly encountered in propulsion systems with the prime objective of providing analytical procedures and design charts capable of dealing with the stringent minimum weight requirements of aerospace vehicles. In general, a method is developed for the solution of the basic equation for circular cylinders subjected to axial symmetric pressures of any type. However, the method was used in this study to obtain dynamic solutions to the more common pressure transient types and the pertinent stresses required for minimum weight design purposes summarized into design charts.

Results of a literature survey are reported in Appendix A. In general, the survey revealed that although the basic equations for the problem at hand are well defined, pertinent dynamic solutions and their application to predicting the correct local stress fields in cylinders subjected to transient pressures were limited.

Transient pressures appear in the form of pressure or rarefraction waves which propagate along ducts at approximately the speed of sound in the contained fluid. These pressure waves have various forms which depend on the nature of the disturbance responsible for them and are discussed in Section II. All dynamic elastic solutions obtained are based on the assumption that the form and velocity of propagation of the pressure transients are known.

The basic equations used in the analysis are derived in Section III. Two solutions are then obtained for the infinite shell, one for the spike load and the other for the step pressure form. In addition, a method for deriving the dynamic response with damping of a finite length duct subjected to axial symmetric pressures is developed. For illustrative purposes, several problems are solved in detail in this Section. The work

is limited to two boundary conditions, i.e. cylinders with both ends simply supported and cylinders with both ends fixed. Although it is shown that the method can be readily used to obtain solutions for all possible combinations of admissable boundary conditions, the two selected boundary conditions are deemed sufficient for practical reasons.

For purposes of presentation of the results of this study in a concise manner convenient for use by the analyst, nondimensional variables and design parameters are introduced in the latter part of Section III. These variables and parameters are introduced into the governing equations and dynamic solutions obtained for the finite length shell are summarized in nondimensional form.

A presentation of typical dynamic response results obtained from the solutions is given in Section IV. In addition, the significance of damping, shear deformation, rotatory inertia, and infinite duct solutions are discussed.

Design charts which yield maximum stresses as a function of the design parameters are presented together with an illustrative example in Section V.

A discussion of the nature of advanced problems which may arise or be significant in ducting problems is presented in Section VI. Finally, conclusions and recommendations are summarized in Section VII.

#### II. TRANSIENT LOAD CONDITIONS

Transient pressures in propulsion systems are created by various means such as opening or closing valves, pump surges, and the flutter of check valves. Such situations are especially severe during rocket engine start or shutdown. In this section, pressure transient conditions of interest are identified, idealized and represented mathematically for analytical purposes. A complete description of the ramp and sinusoidal pressure forms is given.

The most severe transient pressure loading cases to be anticipated are those associated with the rate of valve closure. When a valve is closed, the kinetic energy of the fluid is converted into pressure. A pressure wave then travels along the duct with velocity v. The velocity of propagation of the pressure transient is equal to the speed of sound of the fluid if the walls of the duct are inelastic. However, for elastic ducts, the speed of propagation of the pressure transient may be significantly less than the speed of sound in the fluid (see Reference 2-1).

The peak magnitude of the pressure wave, denoted as p, is indpendent of the rate of valve closure and is only dependent on the initial fluid velocity, mass density of the fluid, and the velocity v, of propagation of the pressure pulse (see Reference 2-1). However, the shape of the pressure transient will depend on the rate of valve closure and for a constant rate of valve closure, the form of the pressure transient, referred to as a ramp, will appear as shown in Figure II-1.

Valve closure time is defined by the symbol  $t_c$ . Thus for instantaneous valve closure time,  $t_c = 0$ , the pressure transient will appear immediately after valve closure as shown in Figure II-2a. The sequence of transient pressures which are induced in a duct when a valve is closed at one end and the other end is attached to a tank is shown in Figure II-2. The end of the duct connected to the tank can be considered as an open end which reflects a pressure front as a rarefaction. Hence the transient pressure during the time interval  $t_0 < t < 2$   $t_0$  will be as shown in Figure II-2b. The time  $t_0 = \ell/v$ , i.e.,  $t_0$  is equal to the time it takes the transient pressure front to traverse the length of the duct.

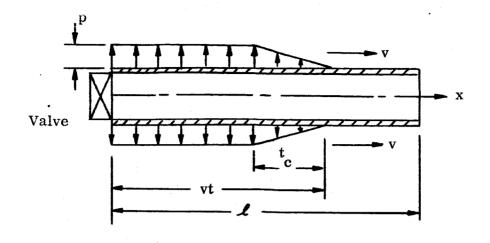

Figure II-1. Ramp Pressure Wave Shape

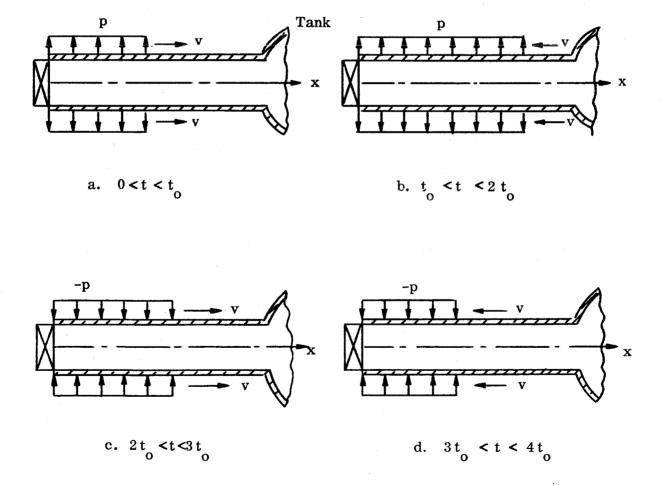

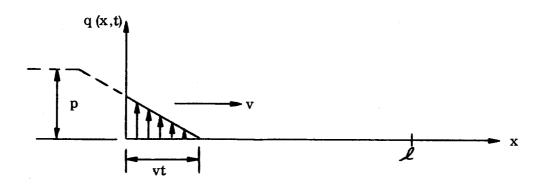

Figure II-2. Step Pressure Wave Shape

Since a closed duct end will reflect a pressure front into a pressure and a rarefaction into a rarefaction, succeeding traverses of the transient pressure will appear as shown in Figures II-2c and II-2d.

All four distinct transient pressure traverses shown in Figure II-2 will be continually repeated in sequence if there is no friction. The presence of friction will tend to decrease the magnitude of the pressure pulse as it traverses the cylinder. In addition, depending on the characteristics of the reflecting media at the ends of the cylinder, there may be a pressure drop with each reflection. In the present study the magnitude of the pressure transient was assumed to remain constant. However, the dynamic solution techniques presented in the next section are not restricted to this assumption.

The description of the ramp pressure transient history which reduces to the step case is now described in detail. It is assumed that the valve closure time,  $t_c$ , is less than the time,  $t_o$ , required for the pressure transient to traverse the cyclinder, i.e.,  $t_c < t_o$ .

For  $0 \le t \le t_c$ 

$$q(x,t) = \frac{-p}{vt} \quad (x - vt)$$

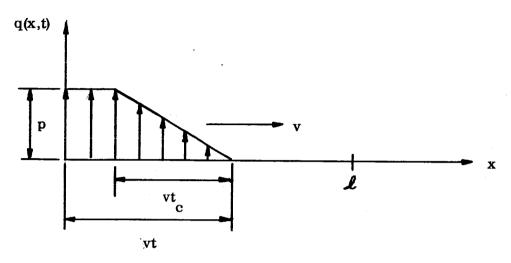

$$q(x,t) = 0$$

$$0 \le x \le vt$$

$$vt \le x \le \mathcal{L}$$

$$(2-1)$$

For  $t_c < t < t_o$ 

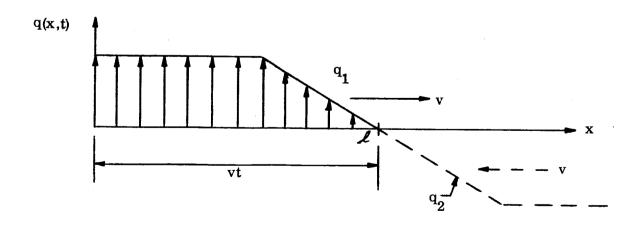

$$q(x,t) = p 0 \le x \le vt - vt_{c}$$

$$q(x,t) = \frac{-p}{vt_{c}} (x - vt) vt_{c} \le x \le vt$$

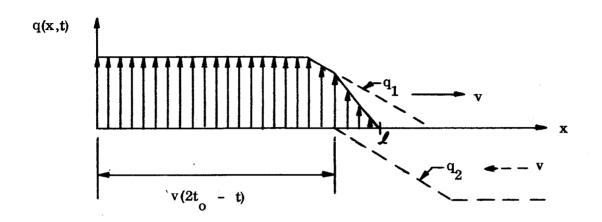

$$q(x,t) = 0 vt \le x \le \mathcal{L}$$

$$(2-2)$$

Succeeding expressions for the transient pressure history are conveniently represented as the superposition of right and left traveling waves. Thus at  $t_0 = \mathcal{L}/v$ , the situation is as shown in the following sketch.

For the time period  $t_0 \le t \le t_0 + t_0$ 

$$q(x,t) = q_1(x,t) + q_2(x,t)$$
  $0 \le x \le \mathcal{L}$  (2-3)

Where the right traveling load is given by

$$q_{1}(x,t) = p \qquad 0 \le x \le vt - vt_{c}$$

$$q_{1}(x,t) = \frac{-p}{vt_{c}} (x - vt) \qquad vt - vt_{c} \le x \le \mathcal{L}$$

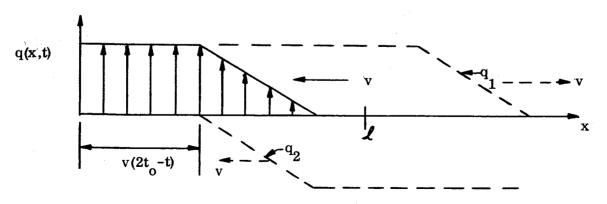

$$(2-4)$$

and the left traveling load is given by

$$q_{2}(x,t) = 0 0 \le x \le 2 \mathcal{L} - vt$$

$$q_{2}(x,t) = \frac{-p}{vt} (x + vt - 2\mathcal{L}) 2\mathcal{L} - vt \le x \le \mathcal{L} (2-5)$$

Similarly for  $t_0 + t_c \le t \le 2 t_0$ 

Right traveling load

$$q_1(x,t) = p$$
  $0 \le x \le \ell$ 

Left traveling load

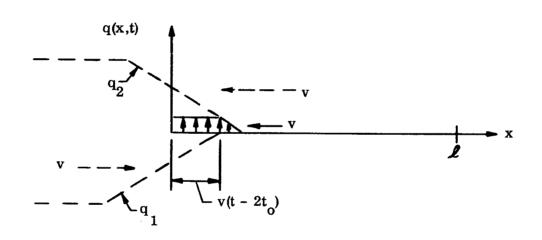

$$q_{2}(x,t) = 0 0 \leq x \leq 2\mathcal{L} - vt$$

$$q_{2}(x,t) = \frac{-p}{vt_{c}} (x + vt - 2\mathcal{L}) 2\mathcal{L} - vt \leq x \leq 2\mathcal{L} - vt + vt_{c} (2-6)$$

$$q_{2}(x,t) = -p 2\mathcal{L} - vt + vt_{c} \leq x \leq \mathcal{L}$$

For

$$2 t_{0} \le t \le 2 t_{0} + t_{0}$$

Right traveling load

$$q_{1}(x,t) = \frac{p}{vt_{c}} (x - vt + 2\ell) \qquad 0 \le x \le vt - 2\ell$$

$$q_{1}(x,t) = 0 \qquad vt - 2\ell \le x \le \ell$$

$$(2-7)$$

Left traveling load

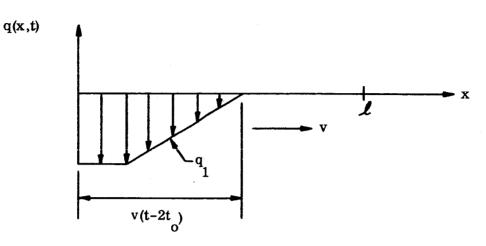

$$q_{2}(x,t) = \frac{-p}{vt} (x + vt - 2 \mathcal{L} - vt_{c}) \qquad 0 \le x \le 2 \mathcal{L} - vt + vt_{c}$$

$$q_{2}(x,t) = 0 \qquad vt - 2 \mathcal{L} + vt_{c} \le x \le \mathcal{L}$$

$$(2-8)$$

For

$$2 t_{o} + t_{c} \le t \le 3 t_{o}$$

Right traveling load

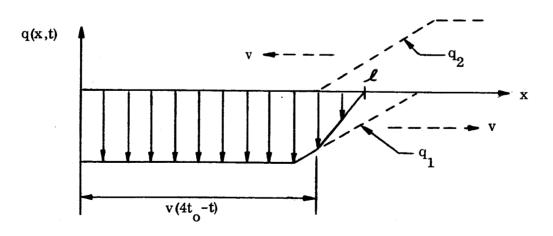

$$q_{1}(x,t) = -p \qquad 0 \le x \le vt - 2\mathcal{L} - vt_{c}$$

$$q_{1}(x,t) = \frac{p}{vt_{c}} (x - vt + 2\mathcal{L}) \qquad vt - 2\mathcal{L} - vt_{c} \le x \le vt - 2\mathcal{L} \qquad (2-9)$$

$$q_{1}(x,t) = 0 \qquad vt - 2\mathcal{L} \le x \le \mathcal{L}$$

For

$$3 t_{o} \le t \le 3 t_{o} + t_{c}$$

Right traveling load

$$q_{1}(x,t) = -p \qquad 0 \le x \le vt - 2\mathcal{L} - vt_{c}$$

$$q_{1}(x,t) = \frac{p}{vt_{c}} (x - vt + 2\mathcal{L}) \qquad vt - 2\mathcal{L} - vt_{c} \le x \le \mathcal{L}$$

$$(2-10)$$

Report No. 2286-950002

Left traveling load

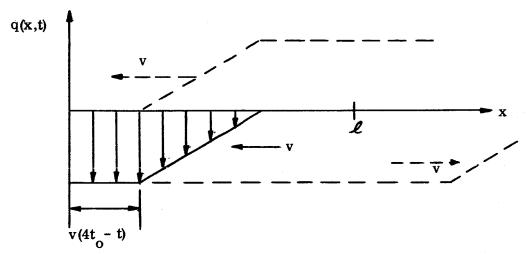

$$q_{2}(x,t) = 0 0 \le x \le 4 \mathcal{L} - vt$$

$$q_{2}(x,t) = \frac{p}{vt} (x + vt - 4 \mathcal{L}) 4 \mathcal{L} - vt \le x \le \mathcal{L}$$

$$(2-11)$$

For

$$3 t_0 + t_c \le t \le 4 t_0$$

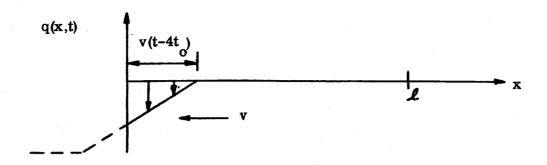

Left traveling load

$$q(\mathbf{x},t) = -\mathbf{p} \qquad 0 \le \mathbf{x} \le 4 \mathcal{L} - \mathbf{v}t$$

$$q(\mathbf{x},t) = \frac{\mathbf{p}}{\mathbf{v}t_{\mathbf{c}}} (\mathbf{x} + \mathbf{v}t - 4\mathcal{L} - \mathbf{v}t_{\mathbf{c}}) \qquad 4\mathcal{L} - \mathbf{v}t \le \mathbf{x} \le 4\mathcal{L} - \mathbf{v}t + \mathbf{v}t_{\mathbf{c}} \qquad (2-12)$$

$$q(\mathbf{x},t) = 0 \qquad 4\mathcal{L} - \mathbf{v}t + \mathbf{v}t_{\mathbf{c}} \le \mathbf{x} \le \mathcal{L}$$

The sequence of pressure transients delineated above corresponds to four complete traverses of the pressure front during the time 4  $t_0$ . This process is continued into the next time interval by superposition of the pressure transient expressions for the first time interval,  $0 \le t \le t_0$ , with the pressure expressions for the last time interval  $t_0 \le t \le t_0 + t_0$  which is defined as follows:

Left traveling load

$$q(\mathbf{x},t) = \frac{\mathbf{p}}{\mathbf{vt_c}} (\mathbf{x} + \mathbf{vt} - 4\boldsymbol{\ell} - \mathbf{vt_c}) \qquad 0 \le \mathbf{x} \le 4\boldsymbol{\ell} - \mathbf{vt} + \mathbf{vt_c}$$

$$q(\mathbf{x},t) = 0 \qquad 4\boldsymbol{\ell} - \mathbf{vt} + \mathbf{vt_c} \le \mathbf{x} \le \boldsymbol{\ell}$$

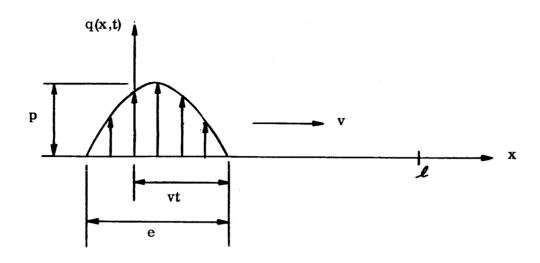

$$(2-13)$$

For valve opening, the form of the pressure transients are essentially the same as the first two traverses described above except that the pressures will be of opposite sign. The sequence of events which occur after these two traverses will depend on the characteristics of the ducting and hardware on the down stream side of the valve.

Impulsive type transient pressures which are caused by pump surges, instability of combustion processes, etc., can be represented by a traveling sinusoidal pressure form. Here, again, it will be assumed that the sinusoidal pulse emanates at the left end of the duct, which thereafter is considered closed, and reflected at the other end which is connected to a relatively large vessel. Thus, as was the case for the ramp pressure form, the right end of the cylinder is assumed open and the left end closed.

The mathematical representation of two traverses of the pressure transient are required to represent the complete characteristics of this transient pressure condition. The sequence of pressure formulas for this case is summarized below. The half wavelength of the assumed sinusoid is denoted by e and it is assumed that  $e \leq \mathcal{L}$ .

At the start of the pressure cycle we have for  $0 \le t \le \frac{e}{v}$ 

$$q(x,t) = -p \sin \pi \frac{(x - vt)}{e}$$

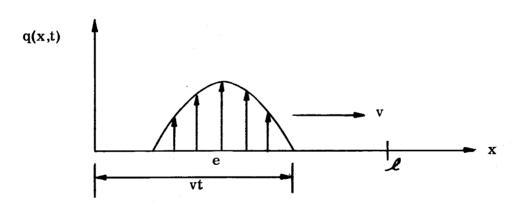

$$0 \le x \le vt$$

$$q(x,t) = 0$$

$$vt \le x \le \mathcal{L}$$
(2-14)

For

$$\frac{e}{v} \le t \le t_{o}$$

$$q(x,t) = 0$$

$$q(x,t) = -p \sin \pi \frac{(x - vt)}{e}$$

$$vt - e \le x \le vt$$

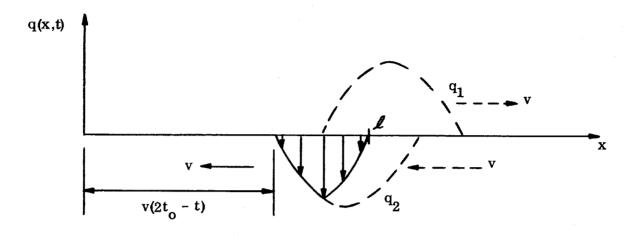

$$q(x,t) = 0$$

$$vt \le x \le \mathcal{L}$$

$$(2-15)$$

The following transient pressure form is represented by the superposition of right and left traveling sinusoid loads. Thus for the interval of time

$$t_0 \le t \le t_0 + \frac{e}{v}$$

Right traveling load

$$q_1(x,t) = 0$$
  $0 \le x \le vt - e$  
$$q_1(x,t) = -p \sin \pi \frac{(x-vt)}{e} \qquad vt - e \le x \le \mathcal{L}$$
 (2-16)

Left traveling load

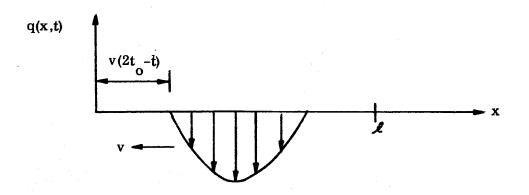

$$q_{2}(x,t) = 0 0 \le x \le 2\mathcal{L} - vt$$

$$q_{2}(x,t) = -p \sin \pi \frac{(x + vt - 2\mathcal{L})}{e} 2\mathcal{L} - vt \le x \le \mathcal{L}$$

$$(2-17)$$

For

$$t_{o} + \frac{e}{v} \le t \le 2 t_{o}$$

$$q(x,t) = 0$$

$$q(x,t) = -p \sin \pi \left(\frac{x + vt - 2\ell}{e}\right)$$

$$q(x,t) = 0$$

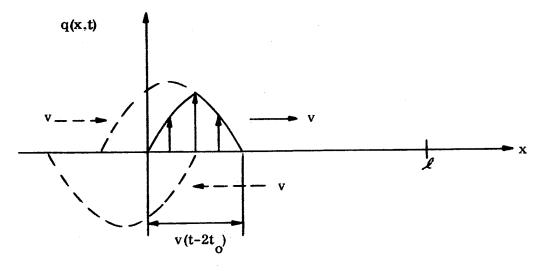

$$0 \le x \le 2\ell - vt$$

$$2\ell - vt \le x \le 2\ell - vt + e$$

$$2\ell - vt + e \le x \le \ell$$

$$2\ell - vt + e \le x \le \ell$$

Finally, the expressions for the interval 2 t  $_0 \le t \le 2$  t  $_0 + \frac{e}{v}$  as shown in the sketch below is given by the superposition of

The right traveling load defined for the interval  $0 \le t \le \frac{e}{v}$  and the left traveling load defined by

$$q(\mathbf{x},t) = -p \sin \pi \frac{(\mathbf{x} + \mathbf{v}t - 2\mathbf{\ell})}{e} \qquad 0 \le \mathbf{x} \le 2\mathbf{\ell} - \mathbf{v}t + e$$

$$q(\mathbf{x},t) = 0 \qquad 2\mathbf{\ell} - \mathbf{v}t + e \le \mathbf{x} \le \mathbf{\ell}$$

$$(2-19)$$

As was the case for the ramp, the defined pressures are used in sequence as time progresses.

In the limit as e -0, and the area under the pressure distribution curve -P the sinusoidal pressure will approach the spike pressure transient case which is illustrated in Figure III-9.

#### III. THEORETICAL DEVELOPMENT

### A. BASIC EQUATIONS

For purposes of the present investigation, the basic structural model is the thin-walled cylindrical shell of circular cross-section. It will be assumed that the shell is made of an elastic, homogeneous, isotropic material, that it is loaded in an axi-symmetric manner, and that its deformation is due to stretching and flexure, shear deformations being neglected for the present. Moreover, it is assumed that the shell wall thickness is small compared to the shell radius, i.e., h << R.

In accordance with these stipulations, a free-body diagram of the shell element is shown in Figure III-1. Summing forces in the w direction and then taking the limit as  $\Delta x \rightarrow 0$ ,  $\Delta \theta \rightarrow 0$  we obtain

$$\frac{\partial Q_{X}}{\partial X} - \frac{N\phi}{R} + \overline{q} = 0 \tag{3-1}$$

Taking moments about an axis which is perpendicular with respect to the X-Z plane and taking the same limit, we obtain

$$Q_{x} + \frac{\partial M_{x}}{\partial x} = 0 \tag{3-2}$$

Equations (3-1) and (3-2) are the equilibrium equations of the shell. The appropriate strain-displacement relations are

$$\epsilon_{x} = \frac{\partial u}{\partial x}, \quad \epsilon_{\phi} = \frac{w}{R}$$
 (3-3)

and the stress-strain relations (Hooke's law) are

$$N_{x} = \frac{Eh}{1-\nu^{2}} (\epsilon_{x} + \nu \epsilon_{\phi})$$

$$N_{\phi} = \frac{Eh}{1-\nu^{2}} (\epsilon_{\phi} + \nu \epsilon_{x})$$
(3-4)

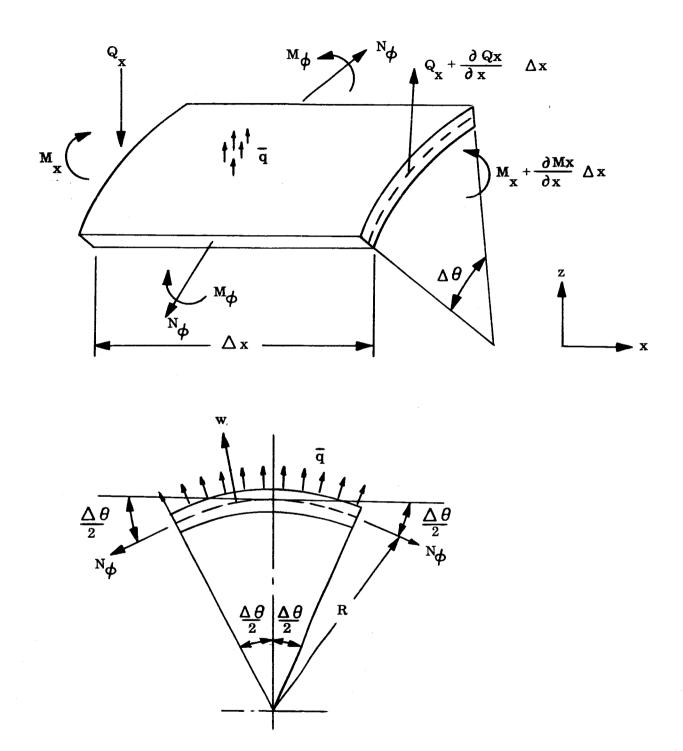

Figure III-1.. Shell Element

It will be assumed (see reference 3-1) that  $N_{X} = 0$ . Upon substitution of equation's (3-3) into equation's (3-4) we have

$$N_{\mathbf{x}} = \frac{Eh}{1-\nu^{2}} \left( \frac{\partial u}{\partial x} + \nu \frac{w}{R} \right) = 0$$

$$N_{\phi} = \frac{Eh}{1-\nu^{2}} \left( \frac{w}{R} + \nu \frac{\partial u}{\partial x} \right) = 0$$
(3-5)

Thus

$$\frac{\partial \mathbf{u}}{\partial \mathbf{x}} = -\frac{\mathbf{w}}{\mathbf{R}} \quad \mathbf{v} \tag{3-6}$$

and

$$N_{\phi} = \frac{Eh}{R} \quad w \tag{3-7}$$

From classical thin-plate theory, we have (Reference 3-2)

$$\mathbf{M}_{\phi} = \mathbf{\nu} \,\mathbf{M}_{\mathbf{x}} \tag{3-8}$$

$$M_{x} = D \frac{\partial^{2} w}{\partial x^{2}}$$
 (3-9)

where D =  $\mathrm{Eh}^3/12(1-\nu^2)$ . Combining equations (3-1), (3-2), (3-7) and (3-9) we obtain

$$D \frac{\partial^4 w}{\partial x^4} + \frac{Eh}{R^2} w = \overline{q}$$
 (3-10)

The normal force intensity  $\overline{q}$  is now decomposed into three distinct parts:

inertia force = 
$$-m \frac{\partial^2 w}{\partial t^2}$$
  
damping force =  $-2c \frac{\partial w}{\partial t}$   
surface traction = q (x, t)

Therefore

$$\overline{q} = q - 2c \frac{\partial w}{\partial t} - m \frac{\partial^2 w}{\partial t^2}$$
(3-11)

and equation (3-10) becomes

$$D \frac{\partial^4 w}{\partial x^4} + \frac{Eh}{R^2} w + 2c \frac{\partial w}{\partial t} + m \frac{\partial^2 w}{\partial t^2} = q(x, t)$$
 (3-12)

Equation (3-12) is regarded as the basic equation for the present investigation.

## B. SHELL OF INFINITE LENGTH

#### 1. Spike Pressure Wave

A solution of equation (3-12) will now be developed for a shell of unbounded length under neglect of damping (c = 0). The shell is assumed to be subjected to a spike loading of magnitude P (ring-line load, see Figure III-2) which translates with uniform speed v in the direction of the shell axis x.

As a prerequisite for a unique solution, we require certain basic physical shell properties with respect to wave propagation along the x-axis. Under neglect of damping and assuming zero surface tractions, equation (3-12) assumes the form

$$D \frac{\partial^4 w}{\partial x^4} + \frac{Eh}{R^2} w + m \frac{\partial^2 w}{\partial t^2} = 0$$
 (3-13)

If we assume the existence of waves of the type

$$\mathbf{w} = \mathbf{e}^{-\mathbf{i} \, (\mathbf{k} \mathbf{x} - \mathbf{\Gamma} \, \mathbf{t})} \tag{3-14}$$

where k is the wave number and  $\Gamma$  is the frequency, and substitute equation (3-14) into equation (3-13), we obtain the following dispersion relation (relation between frequency and wave number):

$$\Gamma = \sqrt{\frac{D}{m} k^4 + \frac{Eh}{m R^2}}$$
 (3-15)

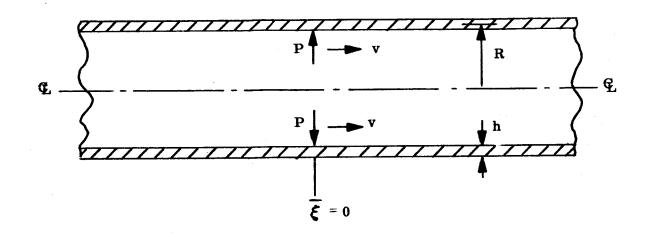

Figure III-2. Infinite Duct ~ Moving Spike

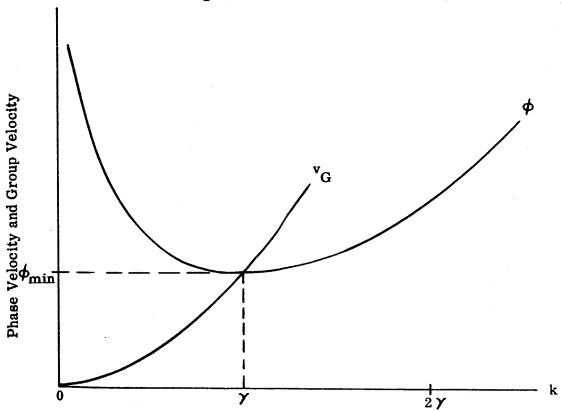

Figure III-3. Phase and Group Velocity versus Wave Number

The phase velocity  $\phi$  is given by (see Reference 3-3)

$$\phi = \frac{\Gamma}{k} = \sqrt{\frac{D}{m} k^2 + \frac{Eh}{mR^2 k^2}}$$
 (3-16)

and the group velocity is

$$v_G = \frac{d\Gamma}{dk} = \frac{\frac{2D}{m}k^3}{\sqrt{\frac{D}{m}k^4 + \frac{Eh}{mR^2}}}$$
 (3-17)

A typical plot of phase and group velocity, using equations (3-16) and (3-17), is shown in Figure III-3. The following general statement can be proved by elementary means with the help of equations (3-16) and (3-17): The minimum phase velocity occurs at the point where the phase velocity and group velocity are equal. At that point, the wave number has the value  $k = \gamma = 4\sqrt{\frac{Eh}{R^2D}}$ . We shall use this result in the subsequent development.

It will be convenient to nondimensionalize the coordinate  $\mathbf{x}$  and to describe the response of the shell in a moving coordinate system. Thus we let

$$\overline{\xi} = (x - v t) \gamma \tag{3-18}$$

where  $\gamma = \sqrt{\frac{Eh}{DR^2}}$ 

If we change variables in equation (3-12) in accordance with equation (3-18) and neglect damping, we obtain

$$\frac{d^4 w}{d \overline{\xi}^4} + 2 \lambda \frac{d^2 w}{d \overline{\xi}^2} + w = \frac{R^2}{Eh} q(\overline{\xi}) \qquad (3-19)$$

where

$$2 \lambda = \frac{\sqrt{12 (1-\nu^2)} \text{ mRv}^2}{\text{Eh}^2}$$
 (3-20)

The change of variable, equation (3-18), may be given the following physical interpretation: An observer fixed with respect to the x-coordinate will see the (spike) load advance in the direction of the positive x-axis, and to him the deflection of the shell will appear to be a function of x and t. However, an observer fixed with respect to the  $\xi$ -axis will move with the advancing load and to him the deflection surface will appear stationary, i.e., independent of t and a function of  $\xi$  alone. We note that by neglecting damped transients due to the starting of the motion, we have made the implicit assumption that the load has been moving for a sufficiently long period. Thus, we shall concentrate on the steady-state dynamical process as characterized by equation (3-19).

A formal solution of equation (3-19) will be obtained by the Fourier Transform Approach. We define the following (complex) Fourier transform pairs:

$$\mathbf{w} (\overline{\xi}) = \sqrt{\frac{1}{2\pi}} \int_{-\infty}^{\infty} \mathbf{w} (\mathbf{a}) e^{-i\overline{\xi}} \mathbf{a} d\mathbf{a}$$
 (3-21a)

$$W(\alpha) = \sqrt{\frac{1}{2\pi}} \int_{-\infty}^{\infty} w(\overline{\xi}) e^{-i\alpha \overline{\xi}} d\overline{\xi}$$
 (3-21b)

$$q(\overline{\xi}) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} Q(\alpha) e^{-i\overline{\xi}\alpha} d\alpha$$
 (3-22a)

$$Q(\alpha) = \sqrt{\frac{1}{2\pi}} \int_{-\infty}^{\infty} q(\overline{\xi}) e^{-i\alpha} \overline{\xi} d\overline{\xi}$$
 (3-22b)

We now Fourier transform equation (3-19) with respect to  $\bar{\xi}$ , i.e., we multiply each term of equation (3-19) by  $e^{-i\alpha \bar{\xi}} d\bar{\xi}$  and integrate between the limits  $-\infty < \bar{\xi} < \infty$  If it is assumed that  $w(\bar{\xi}) \to 0$ ,  $w'(\bar{\xi}) \to 0$ ,  $w''(\bar{\xi}) \to 0$ ,  $w'''(\bar{\xi}) \to 0$  as  $\bar{\xi} \to \pm \infty$  then we obtain

$$W(\alpha) = \frac{R^2}{Eh} \qquad \frac{Q(\alpha)}{(\alpha^4 - 2\lambda \alpha^2 + 1)}$$
(3-23)

Upon substitution of equation (3-23) into equation (3-21a), we obtain the formal solution of equation (3-19):

$$w(\overline{\xi}) = \sqrt{\frac{R^2}{2\pi}} \qquad \frac{1}{Eh} \qquad \int_{-\infty}^{\infty} \frac{Q(\alpha) d\alpha}{(\alpha^4 - 2\lambda \alpha^2 + 1)}$$
(3-24)

To obtain the Fourier transform representation of the spike load, we shall consider the limiting case of a uniformly distributed load. With reference to Figure III-4, we have

$$q(\overline{\xi}) = 0, \qquad \overline{\xi} > |\beta|$$

$$q(\overline{\xi}) = p, \qquad \overline{\xi} < |\beta|$$
(3-25)

Thus, using equation (3-22b), we have

$$Q(\alpha) = \sqrt{\frac{1}{2\pi}} \int_{-\infty}^{\infty} p e^{-i\alpha \xi} d\xi = \sqrt{\frac{\gamma}{2\pi}} \frac{2\beta p}{\gamma} \frac{\sin \alpha \beta}{\alpha \beta}$$

If we now take the limit of  $Q(\alpha)$  as  $\beta - 0$  and  $\frac{2\beta p}{\gamma} - P$  we obtain the Fourier transform representation of the traveling spike load:

$$Q(\alpha) = \frac{\gamma}{2\pi} \qquad P \qquad (3-26)$$

The improper integral in equation (3-24) will now be evaluated, when Q ( $\alpha$ ) is given by equation (3-26), by the method of the calculus of residues. There will be two distinct cases which must be considered: The poles of the integrand in equation (3-24) are (a) complex and (b) real. In case (a) equation (3-24) assumes the form

$$w(\bar{\xi}) = \frac{\gamma_R^2 P}{2 \pi Eh} \int_{-\infty}^{\infty} \frac{e^{-i\bar{\xi} \alpha} d\alpha}{(\alpha - a - ib) (\alpha + a + ib) (\alpha - a + ib) (\alpha + a - ib)}$$
(3-27)

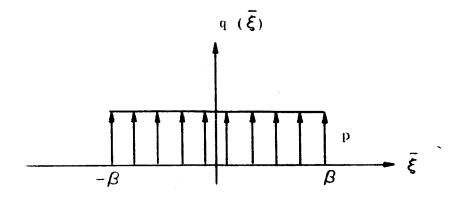

Figure III-4. Load Distribution

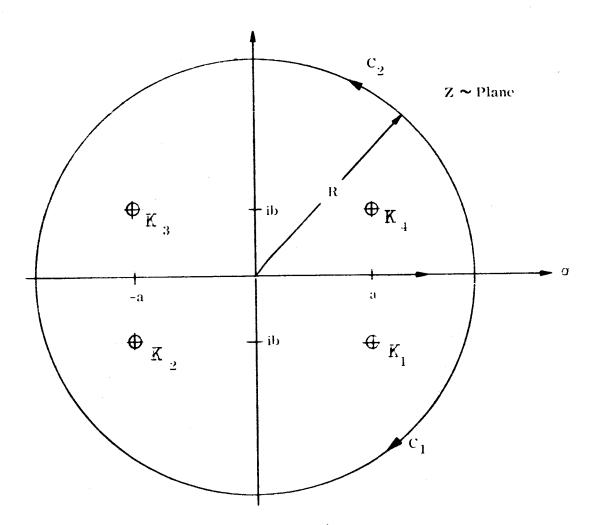

Figure III-5. Contour of Integration,  $\lambda$  < 1, (Spike Load)

where

$$a = \sqrt{\frac{1+\lambda}{2}} \qquad b = \sqrt{\frac{1-\lambda}{2}} \qquad (3-28)$$

and  $\lambda$  < 1. It will be convenient to consider the following contour integral in the complex z plane:

$$I = \oint \frac{e^{-i \bar{\xi} z} dz}{(z-a-ib) (z+a+ib) (z-a+ib) (z+a-ib)}$$
 (3-29)

The contour over which this integral is to be evaluated consists of (see Figure III-5) the upper or lower semi-circle of radius R and the segment of the real axis R > | a | It is easy to show that the line integral, equation (3-29), vanishes for  $\bar{\xi} < 0$  when taken over the upper semi-circle  $C_2$  as R  $\rightarrow \infty$ . Similarly, it vanishes for  $\bar{\xi} > 0$  when taken over the lower semi-circle  $C_1$  as R  $\rightarrow \infty$ . Thus by virtue of the residue theorem we have for  $\bar{\xi} \geq 0$ 

$$w(\bar{\xi}) = \frac{\gamma_R^2 P}{2\pi Eh} \cdot 2\pi i (K_1 + K_2), \ \bar{\xi} \ge 0$$
 (3-30a)

$$w(\bar{\xi}) = \frac{\gamma_R^2 P}{2\pi E h} \cdot 2\pi i (K_3 + K_4), \bar{\xi} \le 0$$
 (3-30b)

where

$$K_{1} = \frac{e^{-i \bar{\xi} - (a-ib)}}{(-2ib) (2a) (2) (a-ib)}$$
(3-31a)

$$K_2 = \frac{e^{-i \bar{\xi} (-a-ib)}}{(2) (-a-ib) (-2a) (-2ib)}$$
(3-31b)

$$K_3 = \frac{e^{-i \xi (-a+ib)}}{(-2a) (2ib) (2) (-a+ib)}$$
 (3-31c)

$$K_4 = \frac{e^{-i \xi (a+ib)}}{(2) (a+ib) (2ib) (2a)}$$
 (3-31d)

Upon combination of equations (3-30) and (3-31) and a certain amount of simplification we obtain the solution of equation (3-19) valid for  $\lambda$  < 1:

$$w(\bar{\xi}) = \frac{R^2 \gamma P}{Eh} \frac{e^{-b\bar{\xi}}}{(4ab)} (a \cos a \bar{\xi} + b \sin a \bar{\xi}), \quad \bar{\xi} \ge 0$$
 (3-32a)

$$w(\bar{\xi}) = \frac{R^2 \gamma P}{Eh} \frac{e^{b\bar{\xi}}}{(4ab)} (a \cos a \bar{\xi} - b \sin a \bar{\xi}), \; \bar{\xi} \leq 0 \qquad (3-32b)$$

where a and b are defined in equation (3-28).

In case (b) where  $\lambda > 1$  we must proceed in a different manner. In this case the poles of the integrand of equation (3-24) lie on the real axis, and it is appropriate to write equation (3-24) as

$$w(\bar{\xi}) = \frac{R^2 \gamma P}{2\pi Eh} \int_{-\infty}^{\infty} \frac{e^{i\bar{\xi}\alpha} d\alpha}{(\alpha + A)(\alpha - A)(\alpha + B)(\alpha - B)}$$
(3-33)

where

A = a + b,  
B = a - b  

$$a = \sqrt{\frac{\lambda + 1}{2}}, \qquad b = \sqrt{\frac{\lambda - 1}{2}}$$
(3-34)

and  $\lambda > 1$ . The improper integral in equation (3-33) will be evaluated by residue calculus, and the method is analagous to the case  $\lambda < 1$  except for the path of integration in the vicinity of the poles (see Figure III-6), where the path is indented. The association of the poles with the upper or lower half plane depends on physical (energy) considerations. With reference to Figure III-3, we note that corresponding to a given phase velocity greater than  $\phi_{\min}$ , there are two wave numbers  $k_1$ ,  $k_2$ , one of them,  $k_1 < \gamma$ , the other  $\gamma < k_2$ . For  $k_2$ , the group velocity is always greater than the phase velocity, and therefore this represents waves moving ahead of the spike at  $\bar{\xi} = 0$ . For the

smaller wave number  $k_1$ , the group velocity is always smaller than the phase velocity, and therefore  $k_1$  corresponds to waves behind the spike. Since energy must travel away from the moving spike disturbance, it becomes clear from the foregoing that the poles at  $\alpha = \pm A$  are associated with the case  $\bar{\xi} > 0$ , while the poles at  $\alpha = \pm B$  are associated with the case  $\bar{\xi} < 0$ . This explains the manner of indentation of the contour in Figure III-6. Thus, invoking the residue theorem we have

$$w(\bar{\xi}) = -\frac{\gamma_R^2 P}{2\pi Eh} \cdot 2\pi i (K_1 + K_2), \bar{\xi} > 0$$
 (3-35a)

$$w(\bar{\xi}) = \frac{\gamma_R^2 P}{2 \pi Eh} \cdot 2 \pi i(K_3 + K_4), \xi < 0$$
 (3-35b)

where  $K_1$ ,  $K_2$   $K_3$  and  $K_4$  are the values of the residue of the integrand function of equation (3-33) at  $\alpha = A$ , -A, B, -B, respectively. These values are given by

$$K_1 = \frac{e^{+i \bar{\xi} A}}{(2A) (A+B) (A-B)}$$
 (3-36a)

$$K_2 = \frac{e^{-i \vec{\xi} A}}{(-2A) (-A+B) (-A-B)}$$
 (3-36b)

$$K_3 = \frac{e^{+i \xi B}}{(B+A) (B-A) (2B)}$$
 (3-36c)

$$K_4 = \frac{e^{-i \bar{\xi} B}}{(A-B) (A+B) (2B)}$$
 (3-36d)

If we now combine equation's (3-35) and (3-36) and simplify, we obtain the solution for  $\lambda > 1$ :

$$\mathbf{w} (\bar{\xi}) = \frac{-\gamma R^2 P}{Eh} \frac{1}{A(A^2 - B^2)} \quad \sin A \bar{\xi}, \; \bar{\xi} > 0$$

$$\mathbf{w} (\bar{\xi}) = \frac{\gamma R^2 P}{Eh} \frac{1}{B(B^2 - A^2)} \quad \sin B \; \bar{\xi}, \; \bar{\xi} < 0$$
(3-37)

where A and B are defined in equation (3-34).

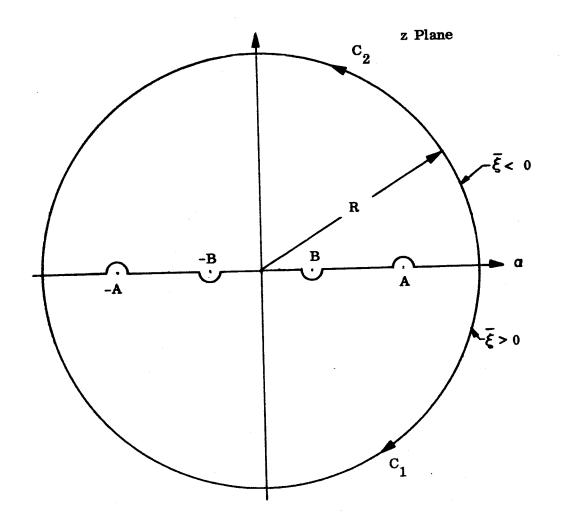

Figure III-6.. Contour of Integration,  $\lambda > 1$ , (Spike Load)

# 2. Step Pressure Wave Shape

We now consider a shell of unbounded length subjected to a uniformly distributed radial pressure load of intensity p advancing in the positive x-direction as shown in Figure III-7. The load is characterized by

$$q = p = constant, \ \overline{\xi} < 0$$

$$q = 0, \qquad \overline{\xi} > 0$$
(3-38)

With reference to Equation (3-19) we have

$$\frac{d^{4}w^{(1)}}{d\bar{\xi}^{4}} + 2\lambda \frac{d^{2}w^{(1)}}{d\bar{\xi}^{2}} + w^{(1)} = 0$$

$$\frac{d^{4}w^{(2)}}{d\bar{\xi}^{4}} + 2\lambda \frac{d^{2}w^{(2)}}{d\bar{\xi}^{2}} + w^{(2)} = \frac{pR^{2}}{Eh}$$
(3-39)

where the superscripts (1) and (2) refer to the region  $\bar{\xi}>0$  and  $\bar{\xi}<0$ , respectively. Solution of Equation (3-39) must be bounded for  $\bar{\xi}\to\pm\infty$ , and at  $\bar{\xi}=0$  we require that the deflection, slope, moment, and shear be continuous, i.e.,

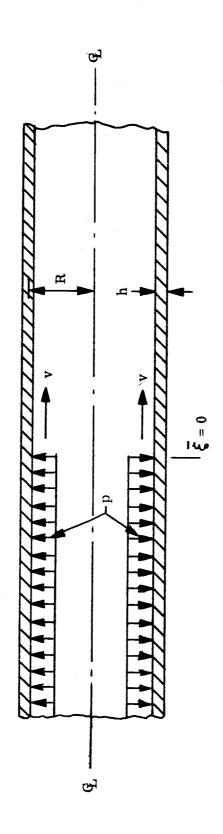

$$\mathbf{w}^{(1)}(0) = \mathbf{w}^{(2)}(0)$$

$$\left(\frac{d\mathbf{w}^{(1)}}{d\mathbf{\xi}}\right)_{\mathbf{\xi}} = 0 = \left(\frac{d\mathbf{w}^{(2)}}{d\mathbf{\xi}}\right)_{\mathbf{\xi}} = 0$$

$$\left(\frac{d^{2}\mathbf{w}^{(1)}}{d\mathbf{\xi}^{2}}\right)_{\mathbf{\xi}} = 0 = \left(\frac{d^{2}\mathbf{w}^{(2)}}{d\mathbf{\xi}^{2}}\right)_{\mathbf{\xi}} = 0$$

$$\left(\frac{d^{3}\mathbf{w}^{(1)}}{d\mathbf{\xi}^{3}}\right)_{\mathbf{\xi}} = 0 = \left(\frac{d^{3}\mathbf{w}^{(2)}}{d\mathbf{\xi}^{3}}\right)_{\mathbf{\xi}} = 0$$

$$(3-40)$$

The characteristic equation obtained by assuming  $\mathbf{w}^{(i)} = \boldsymbol{\rho}^{\alpha} \overline{\boldsymbol{\xi}}$ ,  $i = 1, 2; \alpha = \text{constant}$ , and substituting in the homogeneous Equation (3-39) is:  $\alpha^4 + 2\lambda \alpha^2 + 1 = 0$  (3-41) and its roots are

$$\sqrt{2} \quad \alpha = \pm \left( \sqrt{-\lambda - 1} \quad \pm \quad \sqrt{1 - \lambda} \right) \tag{3-42}$$

Evidently the roots of Equation (3-41) are complex for  $0 < \lambda < 1$  and pure imaginary for  $1 < \lambda$ . Solutions of Equation (3-39) subject to the conditions prescribed by Equation (3-40) and bounded at  $\bar{\xi} \rightarrow \pm \infty$  are found in the usual manner when the roots of the characteristic equation are complex  $(0 < \lambda < 1)$ :

$$\frac{\mathbf{w}^{(1)}}{\mathbf{w}_{0}} = \frac{\mathbf{e}^{-\mathbf{a}\bar{\boldsymbol{\xi}}}}{2} \left( \cos \mathbf{b} \; \bar{\boldsymbol{\xi}} + \frac{\mathbf{a}^{2} - \mathbf{b}^{2}}{2\mathbf{a}\mathbf{b}} \; \sin \mathbf{b} \; \bar{\boldsymbol{\xi}} \right), \; \bar{\boldsymbol{\xi}} \ge 0$$

$$\frac{\mathbf{w}^{(2)}}{\mathbf{w}_{0}} = \frac{\mathbf{e}^{\mathbf{a}\bar{\boldsymbol{\xi}}}}{2} \left( -\cos \mathbf{b} \; \bar{\boldsymbol{\xi}} + \frac{\mathbf{a}^{2} - \mathbf{b}^{2}}{2\mathbf{a}\mathbf{b}} \; \sin \mathbf{b} \; \bar{\boldsymbol{\xi}} \right) + 1, \; \bar{\boldsymbol{\xi}} \le 0$$
(3-43)

where

$$\sqrt{2}$$
 a =  $\sqrt{1-\lambda}$  ;  $\sqrt{2}$  b =  $\sqrt{1+\lambda}$ 
 $w_0 = \frac{p R^2}{Eh}$ 

In the case of pure imaginary roots (1< $\lambda$ ), the solutions of Equation (3-39) are

$$w^{(1)} = C_1^{(1)} \cos a \ \bar{\xi} + C_2^{(1)} \sin a \ \bar{\xi} + C_3^{(1)} \cos b \ \bar{\xi} + C_4^{(1)} \sin b \ \bar{\xi}$$

$$w^{(2)} = C_1^{(2)} \cos b \ \bar{\xi} + C_2^{(2)} \sin b \ \bar{\xi} + C_3^{(2)} \cos a \ \bar{\xi} + C_4^{(2)} \sin a \ \bar{\xi}$$
(3-44)

where

$$\sqrt{2}$$
 a =  $\sqrt{1 + \lambda}$  +  $\sqrt{-1 + \lambda}$ 

$$\sqrt{2}$$
 b =  $\sqrt{1 + \lambda}$  -  $\sqrt{-1 + \lambda}$ 

and there are only four equations (3-40) to determine the eight constants of integration  $C_i^{(j)}$ , i = 1, 2, 3, 4,; j = 1, 2. At this point we may use the concept of group velocity to determine the appropriate steady state motion. The group velocity

is the velocity of energy transport, and the physically appropriate solution requires a flow of energy away from the load front. With reference to Figure III-3, we note that corresponding to a given phase velocity greater than  $\phi_{\min}$ , there are two wave numbers,  $k_1$  and  $k_2$ , one of them  $k_1 < \gamma$ , the other  $\gamma < k_2$ . For  $k_2$ , the group velocity is always greater than the phase velocity, and therefore this represents waves moving ahead of the load front at  $\xi = 0$ . For the smaller wave number  $k_1$ , the group velocity is always smaller than the phase velocity, and therefore  $k_1$  corresponds to waves behind the load front. Since a > b, this argument enables us to set

$$C_3^{(1)} = C_4^{(1)} = C_3^{(2)} = C_4^{(2)} = 0$$

in Equation (3-44). The remaining constants in Equation (3-44) are now determined by applying continuity conditions expressed by Equation (3-40), and the results are  $(1 < \lambda)$ :

$$\frac{\mathbf{w}^{(1)}}{\mathbf{w}_{0}} = -\frac{\mathbf{b}^{2} \cos a \, \bar{\xi}}{a^{2} - \mathbf{b}^{2}} \; ; \; \bar{\xi} \ge 0$$

$$\frac{\mathbf{w}^{(2)}}{\mathbf{w}_{0}} = -\frac{\mathbf{a}^{2} \cos \mathbf{b} \, \bar{\xi}}{a^{2} - \mathbf{b}^{2}} + 1; \; \bar{\xi} \le 0$$
(3-45)

where

$$\sqrt{2}$$
 a =  $\sqrt{1+\lambda}$  +  $\sqrt{-1+\lambda}$ 

$$\sqrt{2}$$
 b =  $\sqrt{1+\lambda}$  -  $\sqrt{-1+\lambda}$ 

$$w_o = \frac{pR^2}{Eh}$$

#### C. SHELL OF FINITE LENGTH

- 1. General Development for Arbitrary Homogeneous Boundary Conditions
  - a. Free Vibrations

We assume a solution of the form

$$\mathbf{w} = \mathbf{W}(\mathbf{x}) \cdot \mathbf{T}(\mathbf{t}) \tag{3-46}$$

of the homogeneous Equation (3-12) (i.e., q = 0). Upon substitution of Equation (3-46) into Equation (3-12), division by W • T, and some re-arrangement, we obtain a separation of variables

$$-\frac{\mathbf{m}}{\mathbf{D}}\frac{\mathbf{T}}{\mathbf{T}} - \frac{2\mathbf{c}}{\mathbf{D}}\frac{\mathbf{T}}{\mathbf{T}} = \frac{\mathbf{W}^{\mathbf{IV}}}{\mathbf{W}} + \frac{\mathbf{Eh}}{\mathbf{DR}^2} = \frac{\mathbf{m}\boldsymbol{\omega}^2}{\mathbf{D}}$$
(3-47)

where  $\omega^2$  is an undetermined constant.

Consequently

$$T + \frac{2c}{m} T + \omega^2 T = 0$$
 (3-48)

and

$$\mathbf{W}^{\mathbf{IV}} - \mathbf{k}^{\mathbf{4}} \mathbf{W} = 0 \tag{3-49}$$

where

$$k^{4} = \frac{m}{D} \omega^{2} - \frac{Eh}{DR^{2}}$$
 (3-50)

The admissible, homogeneous boundary conditions corresponding to Equation (3-49) may be stated as follows:

One member of each of the products

vanishes at x = 0, L.

It can be shown (see Reference 3-4) that for a given set of homogeneous (admissable) boundary conditions there exists a denumerable infinity of mode shapes  $W_n$ ,

 $n=1,\,2,\,3,\,\ldots$  which satisfy Equation (3-49). Moreover, corresponding to each mode shape  $W_n$  there is a natural frequency  $\boldsymbol{\omega}_n$ , and vice versa. These mode shapes satisfy the orthogonality relation

$$\int_{0}^{\ell} W_{m}(x) . W_{n}(x) dx = 0$$
 (3-51)

provided  $m \neq n$ . For instance, when the ends of the shell are simply supported we have

$$W_n = W_n'' = 0$$
, at  $x = 0$  and  $x = \mathcal{L}$  (3-52)

In this case the solution of Equation (3-49) which satisfies the boundary conditions, Equation (3-52), is

$$W_n(x) = \sin \frac{n\pi x}{\ell}, \quad n = 1, 2, 3, ...$$
 (3-53)

and the associated frequencies are

$$\boldsymbol{\omega}_{n}^{2} = \frac{1}{m} \left( \frac{Eh}{R^{2}} + \frac{n^{4} \pi^{4}}{\ell^{4}} D \right)$$
 (3-54)

When the ends of the shell are clamped we require

$$W_n = W_n' = 0$$
 at  $x = 0$  and  $x = \ell$  (3-55)

In this case the mode shapes are given by

$$W_{n}(x) = \cosh k_{n} x - \cos k_{n} x - \alpha_{n} (\sinh k_{n} x - \sin k_{n} x)$$
 (3-56)

where

$$a_n = \frac{\cos k_n \ell - \cosh k_n \ell}{\sin k_n \ell - \sinh k_n \ell}$$

and  $k_n \mathcal{L}$  are the roots of the equation

$$\cos k_n \ell \cdot \cosh k_n \ell = 1$$

Frequencies associated with the mode shapes of Equation (3-56) are given by

$$\omega_n^2 = \frac{D}{m} \left( k_n^4 + \frac{Eh}{DR^2} \right)$$
 (3-57)

where n = 1, 2, 3, ...

#### b. Forced Vibration

We now consider the complete Equation (3-12) and assume a solution of the form

$$w(x, t) = \sum_{n=1, 2...}^{\infty} T_n(t) \cdot W_n(x)$$
 (3-58)

Upon substitution of Equation (3-58) into Equation (3-12), and subsequent utilization of Equation (3-47) we obtain

Both sides of Equation (3-59) are now multiplied by  $W_m(x)$ , and are then integrated over the length of the duct. Upon application of the orthogonality relation, Equation (3-51), we obtain

$$T_{n} + \frac{2c}{m}T_{n} + \omega_{n}^{2}T_{n} = \frac{4}{m \mathcal{L}K_{n}} \int_{0}^{\mathcal{L}} q(x, t) \cdot W_{n}(x) dx \qquad (3-60)$$

where

$$K_{n} = \frac{4}{\mathcal{L}} \int_{0}^{\mathcal{L}} W_{n}^{2} \quad (x) dx \qquad (3-61)$$

The initial conditions for the duct are now translated into the initial conditions on  $T_n$ . At t=0 we have (see Equation (3-58)

$$w(x, o) = w_{o}(x) = \sum_{n=1, 2, ...}^{\infty} T_{n}(o) \cdot W_{n}(x)$$
 (3-62)

$$\dot{\mathbf{w}}(\mathbf{x}, \mathbf{o}) = \dot{\mathbf{w}}_{\mathbf{o}}(\mathbf{x}) = \sum_{n=1, 2, \ldots}^{\infty} \dot{\mathbf{T}}_{n}(\mathbf{o}) \cdot \mathbf{W}_{n}(\mathbf{x})$$
 (3-63)

Multiply Equation (3-62) by  $W_{m}$  (x) and integrate the result over the length of the shell. Upon application of Equation (3-51) we obtain

$$T_n(0) = \frac{4}{\ell K_n} \int_0^{\ell} w_0(x) W_n(x) dx$$
 (3-64)

A similar procedure, when applied to Equation (3-63) results in

$$T_n(0) = \frac{4}{\ell K_n} \int_0^{\ell} w_0(x) W_n(x) dx$$
 (3-65)

It may be concluded that for given mode shapes  $W_n$  (x), load q (x, t), and initial conditions  $w_0$  (x) and  $w_0$  (x), we may calculate the shell response by solving Equation (3-60) subject to initial conditions Equation (3-64) and (3-65). Specific application of the above theory follow.

- 2. Sample Specific Solutions
  - a. Dimensional Form
    - (1) Simple Support
      - (a) Spike

We now consider the specific case of a spike (ring load) traveling with speed v through the duct. The duct is simply supported at x = 0 and x = 2. Thus the eigenfunctions are given by Equation (3-53), and the associated frequencies of free vibration are given by Equation (3-54). It is now required to expand the spike load in an infinite series of the eigenfunctions. This will be accomplished by the expansion of a distributed load of length  $2 \in$  (as shown in Figure III-8), and then taking the limit as

$$q(x, t) = 0, o < x < vt - \epsilon$$

$$q(x, t) = p, vt - \epsilon < x < vt + \epsilon$$

$$q(x, t) = 0, vt + \epsilon < x < \ell$$

$$(3-66)$$

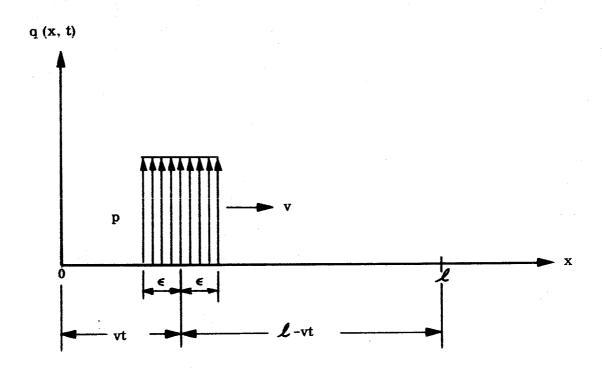

Figure III-8. Spike Load as the Limit of a Distributed Load

Consequently

$$\int_{0}^{\ell} q(x, t) \cdot W_{n}(x) dx = \int_{vt - \epsilon}^{vt + \epsilon} p \sin \frac{n \pi x}{\ell} dx$$

$$= \frac{2p\ell}{n\pi} \sin \frac{n \pi vt}{\ell} \sin \frac{n \pi \epsilon}{\ell}$$

If we now take the limit of this expression as  $\epsilon \rightarrow 0$  and  $2 \epsilon p = P$  we obtain

$$\int_{0}^{\mathcal{L}} q(x, t) \cdot W_{n}(x) dx = P \sin \frac{n \pi vt}{\mathcal{L}}$$
(3-67)

For the return cycle we have

$$q(x, t) = 0,$$
  $0 < x < 2\ell - vt - \epsilon$ 

$$q(x, t) = -p,$$
  $2\ell - vt - \epsilon < x < 2\ell - vt + \epsilon$ 

$$q(x, t) = 0,$$
  $2\ell - vt + \epsilon < x < \ell$ 

and we have

$$\int q(x, t) \cdot W_{n}(x) dx = -\int_{2 - vt - \epsilon}^{2 - vt - \epsilon} p \sin \frac{n \pi x}{\ell} dx$$

$$= \frac{2pl}{n \pi} \sin \frac{n \pi vt}{\ell} \sin \frac{n \pi \epsilon}{\ell}$$

as before. We may continue this process and show that for the three cycles shown in Figure III-9 the expression, Equation (3-67) holds with appropriate time intervals as indicated in Figure III-9. We also note that for the simply supported duct (see Equations (3-61) and (3-53)

$$K_{n} = \frac{4}{\mathcal{L}} \int_{0}^{\mathcal{L}} W_{n}^{2} dx = \frac{4}{\mathcal{L}} \int_{0}^{\mathcal{L}} \left( \sin \frac{n \pi x}{\mathcal{L}} \right)^{2} dx = 2$$
 (3-68)

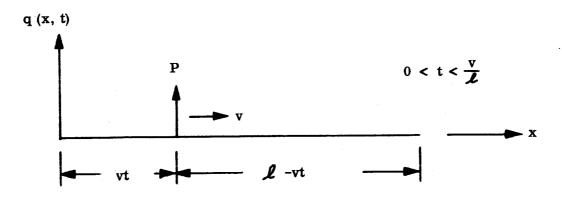

Figure III-9a

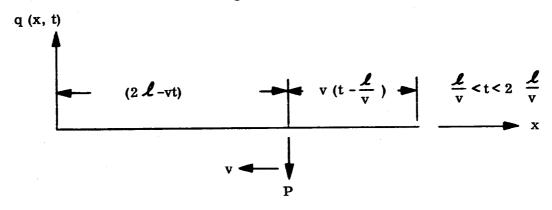

Figure III-9b

P  $2\frac{\ell}{v} < t < 3\frac{\ell}{v}$   $vt - 2\ell$   $vt - 2\ell$ 

Figure III-9c

Figure III-9. Moving Spike Load

Combining Equations (3-67), (3-68), and (3-60) we obtain

$$T_{n} + \frac{2c}{m} T_{n} + \omega_{n}^{2} T_{n} = \frac{2}{mL} P \sin \frac{n\pi vt}{L}$$
 (3-69)

It is now assumed that the duct is undisturbed with respect to displacement and velocity at t = 0. Thus, from Equations (3-64) and (3-65) we have the initial conditions

$$T_n(0) = T_n(0) = 0$$
 (3-70)

With the assumption that damping is below its critical value, i.e.,  $\omega_n^2 > (c/m)^2$ , the solution of Equation (3-69) subject to the initial conditions, Equation (3-70) is given by

$$T_{n}(t) = \frac{\frac{2p}{m \ell \omega_{n}^{2}}}{\left[\left(1 - \frac{a^{2}}{\omega_{n}^{2}}\right)^{2} + \left(\frac{2ca}{m \omega_{n}^{2}}\right)^{2}\right]} \left\{ae^{-\frac{c}{m}t}\left(\frac{2c}{m \omega_{n}^{2}}\right)\cos\overline{\omega}_{n}t + \frac{1}{\overline{\omega}_{n}}\left[\frac{2c^{2}}{m^{2}\omega_{n}^{2}} - \left(1 - \frac{a^{2}}{\omega_{n}^{2}}\right)\right]\sin\overline{\omega}_{n}t + \left(1 - \frac{a^{2}}{\omega_{n}^{2}}\right)\sin at - \frac{2ca}{m \omega_{n}^{2}}\cos at\right\}$$

$$(3-71)$$

where

$$a = \frac{n \pi v}{t}$$

$$\bar{\omega}_n^2 = \omega_n^2 \left[ 1 - \left( \frac{c}{m \omega_n} \right)^2 \right]$$

$$\omega_n^2 = \frac{D}{m N^4} \left[ \frac{Eh N^4}{DR^2} + n^4 \pi^4 \right]$$

$$D = \frac{Eh^3}{12 (1 - v^2)}$$

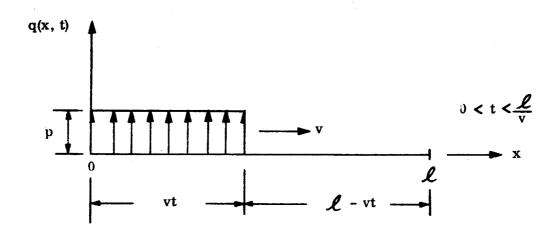

Figure III-10a

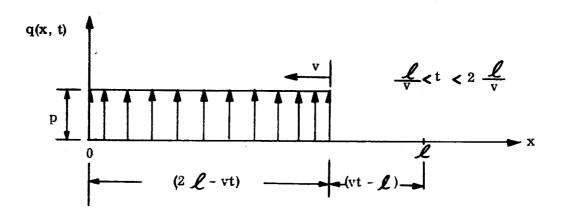

Figure III-10b

Figure III-10. Moving Step Load

Thus the complete solution for the simply supported shell, applicable to the loading cases indicated in Figure III-9, and appropriately restricted to the time intervals indicated in the figure, is given by

$$w = \sum_{n=1}^{\infty} T_n(t) \sin \frac{n\pi x}{\ell}$$
 (3-72)

where  $T_n$  (t) is defined in Equation (3-71).

## (b) Step

We now calculate the response of a simply supported cylindrical duct to a uniformly distributed pressure load in the form of a step moving in the direction of the duct axis. We shall neglect damping in the subsequent calculations, i.e., c = 0. In this case we have (see Figure III-10a)

$$q(x, t) = p,$$
  $0 < x < vt$   
 $q(x, t) = 0,$   $vt < x < \ell$  (3-73)

Consequently, for  $0 < t < \frac{1}{v}$  we have

$$\int_{0}^{\ell} q(x, t) \cdot W(x) dx = \int_{0}^{vt} p \sin \frac{n\pi x}{\ell} dx$$

$$= \frac{p \mathcal{L}}{n \pi} \left( 1 - \cos \frac{n \pi vt}{\mathcal{L}} \right) \tag{3-74}$$

For the unloading phase  $\frac{l}{v} < t < 2 \frac{l}{v}$  as shown in Figure III-10, we have

$$q(x, t) = p,$$
  $0 < x < 2\ell - vt$   
 $q(x, t) = 0,$   $2\ell - vt < x < \ell$  (3-75)

and 
$$\int_{0}^{\ell} q(x, t) \cdot W(x) dx = \int_{0}^{2\ell - vt} p \sin \frac{n \pi x}{\ell} dx = \frac{p\ell}{n\pi} \left( 1 - \cos \frac{n \pi vt}{\ell} \right)$$
(3-76)

Substitution of Equations (3-68) and (3-74) into Equation (3-60) (with c=0) results in

$$T_{n} + \omega_{n}^{2} T_{n} = \frac{2p}{mn\pi} \left( 1 - \cos \frac{n\pi vt}{\mathcal{L}} \right)$$
 (3-77)

The initial conditions are expressed by Equation (3-70). The solution of Equation (3-77) subject to initial conditions, Equation (3-70), is  $\left(\omega_n \neq \frac{n \pi v}{\ell}\right)$ 

$$T_{n}(t) = \frac{2 p n \pi v^{2}}{m \ell^{2}} \frac{\cos \omega_{n} t}{\omega_{n}^{2} \left(\omega_{n}^{2} - \frac{n^{2} \pi^{2} v^{2}}{\ell^{2}}\right)}$$

$$+\frac{2p}{mn\pi} \left[ \frac{1}{\boldsymbol{\omega}_{n}^{2}} - \frac{\cos \frac{n\pi vt}{\boldsymbol{\ell}}}{\left(\boldsymbol{\omega}_{n}^{2} - \frac{n^{2}\pi^{2} v^{2}}{\boldsymbol{\ell}^{2}}\right)} \right]$$
(3-78)

where

$$\boldsymbol{\omega}_{n}^{2} = \frac{D}{m\boldsymbol{\ell}^{4}} \begin{bmatrix} \frac{Eh\boldsymbol{\ell}^{4}}{DR^{2}} + n^{4} & \boldsymbol{\pi}^{4} \end{bmatrix}$$

Thus, the response of the simply supported duct to the moving pressure load shown in Figure III-10 is given by Equation (3-72), where  $T_n$  (t) is expressed by Equation (3-78), and t is suitably restricted as indicated in Figure III-10.

## (2) Clamped-Clamped

### (a) Spike

In calculating the response of a clamped duct to a propagating disturbance in the form of a spike we apply the limiting procedure, as before, to a uniformly distributed load over the length  $2 \in \mathbb{R}$ . Thus the load distribution is given by Equation (3-66), but the eigenfunctions are characterized by Equation (3-56).

Consequently

$$\int_{0}^{2} q(x, t) \cdot W_{n}(x) dx = p \int_{vt - \epsilon}^{vt + \epsilon} \left[ \cosh k_{n} x - \cos k_{n} x - \alpha_{n} \left( \sinh k_{n} x - \sin k_{n} x \right) \right] dx$$

$$= \frac{2p}{k_n} \left( \sinh k_n \epsilon \cosh k_n vt - \sin k_n \epsilon \cos k_n vt - \sin k_n \epsilon \cos k_n vt - \alpha \sinh k_n vt \sinh k_n \epsilon + \alpha \sinh k_n vt \sin k_n \epsilon \right)$$

$$(3-79)$$

We now take the limit of Equation (3-79) as  $\epsilon \rightarrow 0$  and 2 p  $\epsilon \rightarrow P$ 

$$\int_{0}^{\mathcal{L}} q(x, t) W_{n}(x) dx = P \qquad \left( \cosh k_{n} vt - \cos k_{n} vt \right)$$

$$- \boldsymbol{a}_{n} \sinh k_{n} vt + \boldsymbol{a}_{n} \sin k_{n} vt$$
 (3-80)

We also note that in the case of a clamped duct (see Reference 3-4)

$$\int_{0}^{\mathcal{L}} W_{n}^{2}(x) dx = \frac{\mathcal{L}}{4} K_{n}$$

where

$$K_{n} = \left[\frac{d^{2}W_{n}}{d(k_{n}x)^{2}}\right]^{2}$$

$$x = \int_{0}^{\infty} d^{2}W_{n}$$
(3-81)

Upon substitution of Equation (3-56) into Equation (3-81) we obtain

$$\mathbf{K}_{n} = \left[ \cosh \mathbf{k}_{n} \ell + \cos \mathbf{k}_{n} \ell - \alpha_{n} \left( \sinh \mathbf{k}_{n} \ell + \sin \mathbf{k}_{n} \ell \right) \right]^{2} = 4$$
 (3-82)

Combining Equations (3-60), (3-80), and (3-82) we obtain

$$T_n + \omega_n^2 T_n = \frac{P}{m \mathcal{L}} \left( \cosh k_n \text{ vt - } \cos k_n \text{ vt - } \alpha_n \sinh k_n \text{ vt + } \alpha_n \sin k_n \text{ vt} \right)$$
(3-83)

The solution of Equation (3-83) for the non-resonant case

$$\boldsymbol{\omega_n}^2 = \frac{D}{m\boldsymbol{\ell}^4} \left( \frac{Eh\boldsymbol{\ell}^4}{DR^2} + k_n^4 \boldsymbol{\ell}^4 \right) \neq k_n^2 v^2$$

and for initial conditions, Equation (3-70), is

$$T_n(t) = A_n \cos \omega_n t + B_n \sin \omega_n t$$

$$+\frac{\mathbf{P}}{\mathbf{m} \mathbf{\ell}} \left( \frac{\cosh k_{n} vt - \boldsymbol{\alpha}_{n} \sinh k_{n} vt}{\boldsymbol{\omega}_{n}^{2} + k_{n}^{2} v^{2}} + \frac{\boldsymbol{\alpha} \sin k_{n} vt - \cos k_{n} vt}{\boldsymbol{\omega}_{n}^{2} - k_{n}^{2} v^{2}} \right)$$
(3-84)

where

$$A_{n} = \frac{2P}{m \mathcal{L}} \qquad \frac{k_{n}^{2} v^{2}}{\left(\omega_{n}^{4} - k_{n}^{4} v^{4}\right)}$$

$$B_{n} = -\frac{2 \alpha_{n}^{P} k_{n}^{3} v^{3}}{m \mathcal{L} \omega_{n}} \cdot \frac{1}{\omega_{n}^{4} - k_{n}^{4} v^{4}}$$

and the complete solution valid for  $0 < t < \frac{\ell}{V}$  corresponding to the moving spike in a clamped shell is given by Equation (3-72), where  $T_n$  (t) is represented by Equation (3-84).

#### (b) Step

The loading is shown in Figure III-10a and is expressed by Equation (3-73). It is applied to a clamped duct. Thus, for  $0 < t < \frac{L}{V}$ ,

$$\int_{0}^{L} q(x, t) W_{n}(x) dx = \int_{0}^{wt} p\left(\cosh k_{n} x - \cos k_{n} x\right)$$

$$- \alpha_{n} \sinh k_{n} x + \alpha_{n} \sin k_{n} x\right) dx = \frac{p}{k_{n}} \left(\sinh k_{n} vt - \sin k_{n} vt\right)$$

$$- \alpha_{n} \cosh k_{n} vt - \alpha_{n} \cos k_{n} vt + 2\alpha_{n}\right)$$
(3-85)

Combining Equations (3-60), (3-85) and (3-82), we obtain (without damping c = 0)

$$T_{n} + \omega_{n}^{2} T_{n} = \frac{p}{m \ell k_{n}} \left( \sinh k_{n} vt - \sin k_{n} vt - \alpha_{n} \cosh k_{n} vt - \alpha_{n} \cos k_{n} vt + 2 \alpha_{n} \right)$$

$$(3-86)$$

The solution of Equation (3-86) subject to initial conditions, Equation (3-70), is given by (  $\omega_n^2 \neq k_n^2 v^2$ ):

$$T_{n}(t) = A_{n} \cos \omega_{n} t + B_{n} \sin \omega_{n} t + \frac{p}{m \ell k_{n}} \qquad \left(\frac{\sinh k_{n} vt - \alpha_{n} \cosh k_{n} vt}{\omega_{n}^{2} + k_{n}^{2} v^{2}}\right)$$

$$-\frac{\sin k_{n} vt + \alpha_{n} \cos k_{n} vt}{\omega_{n}^{2} - k_{n}^{2} v^{2}} + \frac{2\alpha_{n}}{\omega_{n}^{2}}\right)$$

$$(3-87)$$

where

$$\mathbf{A}_{\mathbf{n}} = \frac{2\mathbf{p} \, \boldsymbol{\alpha}_{\mathbf{n}}}{\mathbf{m} \, \boldsymbol{\ell} \, \mathbf{k}_{\mathbf{n}}} \left( \frac{\boldsymbol{\omega}_{\mathbf{n}}^{2}}{\boldsymbol{\omega}_{\mathbf{n}}^{4} - \mathbf{k}_{\mathbf{n}}^{4} \mathbf{v}^{4}} + \frac{1}{\boldsymbol{\omega}_{\mathbf{n}}^{2}} \right)$$

$$B_{n} = \frac{2pv^{3}k_{n}^{2}}{m \boldsymbol{\ell} \boldsymbol{\omega}_{n}} \left(\frac{1}{\boldsymbol{\omega}_{n}^{4} - k_{n}^{4}v^{4}}\right)$$

Thus the complete solution valid for  $0 < t < \frac{L}{v}$  corresponding to the moving spike in a clamped shell is given by Equation (3-72), where  $T_n(t)$  is characterized by Equation (3-87).

#### b. Dimensionless Form

The preceding sample solution for shells of finite length were derived in dimensional form and clearly illustrate the solution technique. However, design charts presented in this report are nondimensional and consequently for convenience in their preparation solutions were derived directly in nondimensional form using the nondimensional form of Equation (3-60) which is given by Equation (3-109). Thus  $\mathbf{T}_n$  is essentially replaced by its nondimensional counterpart  $\mathbf{F}_n$ . The procedures used to determine directly the nondimensional solutions, which are summarized in Section II-E are outlined below for the ramp and sinusoidal pressure transients. Reference in the following is made to equations in Section II-D and II-E and therefore it is suggested that they be read first.

## (1) Simple Supports

### (a) Ramp

Substitution of  $A_n(\tau)$  as given by Equation [3-114] into Equation [3-109] yields the differential equations for the time dependent function  $F_n(\tau)$  for the ramp. Thus for the first two time intervals  $0 \le \tau \le \tau_c$  and  $\tau_c \le \tau \le 1$  (refer to Figure III-12a) we obtain respectively for  $0 \le \tau \le \tau_c$ ;  $(F_n = F_n)$ 

$$\frac{d^{2}F_{n}}{d\tau^{2}} + 2\bar{a}\frac{dF_{n}}{d\tau} + \Omega_{n}^{2} F_{n} = \frac{\beta}{\lambda K_{n}} \left[\frac{\tau}{\tau_{c}} - \frac{1}{K_{n}\tau_{c}} \sin K_{n}\tau\right]$$
for  $\tau_{c} \leq \tau \leq 1$ ;  $(F_{n} = F_{n})$  (3-88)

$$\frac{d^{2}F_{n}}{d\tau^{2}} + 2\overline{a} \frac{dF_{n}}{d\tau} + \Omega_{n}^{2} \qquad F_{n} = \frac{\beta}{\lambda K_{n}} \left[ 1 - \frac{1}{K_{n} \tau_{c}} \left( \sin K_{n} \tau - \sin K_{n} (\tau - \tau_{c}) \right) \right]$$
(3-89)

The general form at the solution of these second order differential equations is given by Equation 3-120. The constants of integration  $A_1$  and  $B_1$  in the solution

for the first time interval  $0 \le \tau \le \tau$  are obtained from the following initial conditions (refer Equation 3-70).

$$\mathbf{F}_{\mathbf{n}_1}$$
 (o) = 0 (3-90)

$$\frac{d \mathbf{F}_{n_1}(0)}{d \mathbf{T}} = 0$$

The constants of integration  $A_{2n}$  and  $B_{2n}$  in the solution for the second time interval  $\tau_c \le \tau \le 1$  are determined from the conditions at time  $\tau = \tau_c$ . These conditions are

$$F_{n_1}$$
  $(\tau_c) = F_{n_2}(\tau_c)$ 

$$\frac{\mathrm{d}\mathbf{F}_{\mathbf{n}}}{\mathrm{d}\boldsymbol{\tau}} (\boldsymbol{\tau}_{\mathbf{c}}) = \frac{\mathrm{d}\mathbf{F}_{\mathbf{n}}}{\mathrm{d}\boldsymbol{\tau}} (\boldsymbol{\tau}_{\mathbf{c}}) \tag{3-91}$$

Finally, the solutions to Equations [3-88] and [3-89], subjected to initial conditions of Equations (3-90) and (3-91) are given by Equations (3-120) and (3-124).

#### (b) Sinusoid

The governing differential equations for the time dependent function  $F_n$  ( $\tau$ ) for the sinusoid are obtained from Equations [3-109] and [3-115]. Thus for the time intervals  $0 \le \tau \le \epsilon$  and  $\epsilon \le \tau \le 1$  (refer Figure III-12b) we have respectively  $0 \le \tau \le \epsilon$ ; ( $F_n = F_n$ )

$$\frac{d^2 F_n}{d\tau^2} + 2 \overline{\alpha} \frac{d F_n}{d \tau} + \Omega_n^2 \qquad F_n = \frac{\beta}{\lambda K_n} \left[ \frac{n \epsilon}{1 - \epsilon^2 n^2} \left( \sin K_n^{\tau} - n \epsilon \sin \frac{\pi \tau}{\epsilon} \right) \right]$$

(3-92)

$$\epsilon \leq \tau \leq 1; \quad (F_n = F_{n_2})$$

$$\frac{d^{2} F_{n}}{d\tau^{2}} + 2 \overline{a} \frac{d F_{n}}{d\tau} + \Omega_{n}^{2} F_{n} = \frac{\beta}{\lambda K_{n}} \left[ \frac{n \epsilon}{1 - \epsilon^{2} n^{2}} \left( \sin K_{n}^{\tau} + \sin K_{n} (\tau^{-\epsilon}) \right) \right]$$
(3-93)

The initial conditions for Equation (3-92) are (refer to Equation 3-70)

$$F_{n_1}(0) = 0$$

$$\frac{dF_{n_1}(0)}{dT} = 0$$
(3-94)

The constants of integration for Equations (3-92) and (3-93) are obtained for conditions which must be satisfied at  $\tau = \epsilon$ . These conditions are

$$F_{n_{1}}(\epsilon) = F_{n_{2}}(\epsilon)$$

$$\frac{dF_{n_{1}}(\epsilon)}{d\tau} = \frac{dF_{n_{2}}(\epsilon)}{d\tau}$$
(3-95)

The solutions to Equations (3-92) and (3-93) which satisfy Equations (3-94) and (3-95) are given by Equations (3-120) and (3-125).

- (2) Clamped Clamped
  - (a) Ramp

Equations (3-109) and (3-117) yield the differential equations for the time dependent function  $F_n(\tau)$  for the ramp and clamped-clamped boundary condition. The

differential equations for the intervals  $0 \le \tau \le \tau$  and  $\tau_c \le \tau \le 1$  are given by

$$0 \le \tau \le \tau$$
 c;  $(\mathbf{F}_n = \mathbf{F}_{n_1})$ 

$$\frac{d^{2}F_{n}}{d\tau^{2}} + 2\bar{\sigma} \frac{dF_{n}}{d\tau} + \Omega^{2}_{n}F_{n} = \frac{\beta}{2\lambda K_{n}^{2}\tau_{c}} \left[ \left( \cosh K_{n}^{\tau} + \cos K_{n}^{\tau} - 2 \right) - \bar{\alpha}_{n} \left( \sinh K_{n}^{\tau} + \sin K_{n}^{\tau} \right) + 2K_{n}^{\alpha} \alpha_{n}^{\tau} \right]$$
(3-96)

$$\tau_c \le \tau \le 1$$
;  $(F_n = F_{n_2})$ 

$$\frac{d^{2}F_{n}}{d\tau^{2}} + 2\bar{\alpha}\frac{dF_{n}}{d\tau} + \Omega_{n}^{2} F_{n} = \frac{\beta}{2\lambda K_{n}^{2}\tau_{c}} \left[ \left( \cosh K_{n}\tau - \cosh K_{n}(\tau - \tau_{c}) \right) + \left( \cosh K_{n}\tau - \cosh K_{n}(\tau - \tau_{c}) \right) - \alpha_{n} \left( \sinh K_{n}\tau - \sinh K_{n}(\tau - \tau_{c}) \right) - \alpha_{n} \left( \sinh K_{n}\tau - \sinh K_{n}(\tau - \tau_{c}) \right) + 2K_{n}\alpha_{n}\tau_{c} \right]$$

$$(3-97)$$

The solutions to Equations (3-96) and (3-97) are obtained with initial conditions given by Equations (3-90) and (3-91) and are given by Equations (3-120) and (3-128).

# (b) Sinusoid.

For this case the differential equations for  $F_n$  ( $\tau$ ) are obtained from Equations (3-109) and (3-118). Thus for the time periods  $0 \le \tau \le \epsilon$  and  $\epsilon \le \tau \le 1$  (refer to Figure III-12) we have

for 
$$0 \le \tau \le \epsilon$$
;  $(F_n = F_{n_1})$ 

$$\frac{d^{2}F_{n}}{d\tau^{2}} + 2\overline{\alpha} \frac{dF_{n}}{d\tau} + \Omega^{2} \frac{1}{n} F_{n} = \frac{\beta \epsilon}{2\lambda \pi} \left[ \cos \frac{\pi \tau}{\epsilon} - \cosh \frac{\pi \tau}{\epsilon} + \frac{\tau \pi}{\epsilon} \sin \frac{\pi \tau}{\epsilon} - \alpha \left( 2 \sin \frac{\pi \tau}{\epsilon} - \sinh \frac{\pi \tau}{\epsilon} - \frac{\pi \tau}{\epsilon} \cos \frac{\pi \tau}{\epsilon} \right) \right]$$

$$(3-98)$$

for 
$$\epsilon \leq \tau \leq 1$$
;  $(F_n = F_{n_2})$ 

$$\frac{d^{2}F_{n}}{d\tau^{2}} + 2\overline{a} \frac{dF_{n}}{d\tau} + \Omega^{2}_{n}F_{n} = \frac{\beta \epsilon}{2\lambda \pi} \left[ \cosh \frac{\pi \tau}{\epsilon} + \cosh \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi \tau}{\epsilon} \sin \frac{\pi \tau}{\epsilon} + \frac{\pi (\tau - \epsilon)}{\epsilon} \sin \frac{\pi \tau}{\epsilon} - \alpha_{n} \left( \sinh \frac{\pi \tau}{\epsilon} + \sinh \frac{\pi (\tau - \epsilon)}{\epsilon} + \frac{\pi \tau}{\epsilon} \cos \frac{\pi \tau}{\epsilon} \right]$$

$$+ \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} \left( 3 - 99 \right)$$

The solutions to these differential equations are obtained with initial conditions of Equations (3-94) and (3-95) and are given by Equations (3-120) and (3-129).

# D. NONDIMENSIONALIZATION AND DESIGN PARAMETERS

From a designer's point of view, it is desirable to reduce the number of design charts to a minimum. This is accomplished by the introduction of design parameters which combine as many of the problem variables as possible. From a nondimensionalization of the elastic response solutions obtained for the infinite and finite length cylinder, three independent design parameters were indicated. These are designated as the speed parameter,  $\lambda$ , length parameter,  $\beta$ , and damping parameter,  $\alpha$ .

The speed parameter,  $\lambda$ , was introduced quite naturally earlier in the determination of the dynamic solution for the infinite shell (see Equation 3-20) and is defined as follows:

$$\lambda = \frac{\rho \ v^2}{2 \text{ Eg}} \frac{R}{h} \sqrt{12 \ (1 - \nu \ 2)}$$
 (3-100)

where v is the speed of the pressure transient front and  $\rho$  is the weight density of the cylinder material. It is significant to note that  $\lambda$  is equal to the ratio of the squares of the speed of the traveling pressure transient and the critical speed for an infinitely long cylinder.

For convenience for the determination of  $\lambda$ , Figure III-11 was prepared and gives  $\lambda$  directly as a function of the velocity of the pressure transient and the expression  $\frac{\rho\sqrt{1-\nu^2}}{E}$ . It appears that for many materials we have  $\frac{\rho\sqrt{1-\nu^2}}{E}=0.95 \times 10^{-8}$ . Examination of Figure III-11 indicates that the practical range of values for  $\lambda$  is  $0 < \lambda < 6$ . However, values of  $\lambda \ge 10$  are possible. In general, small values of  $\lambda$  will govern in the relatively thick walled piping systems of the smaller propulsion systems whereas large values of  $\lambda$  prevail for the relatively large thin walled ducts used in big booster propulsion systems.

The two remaining independent design parameters are the length parameter defined as

$$\beta = \frac{\ell^2}{Rh} \sqrt{12(1-\nu^2)}$$
 (3-101)

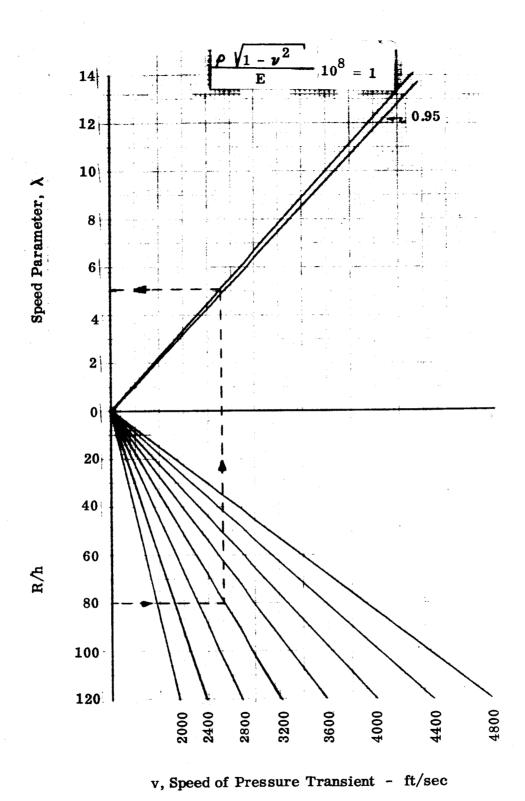

Figure III-11. Graphical Determination of Speed Parameter

and the damping parameter defined as

$$\alpha = \frac{cR}{h} \sqrt{\frac{g}{\rho E}}$$
 (3-102)

where c is the viscous damping coefficient.

From an examination of the various cylinder geometries of interest in propulsion systems, it was found that the length parameter can vary over a relatively large range primarily due to the  $\mathcal{L}^2$  term. However, it appears that for most practical circumstances  $\beta$  will vary in the range

$$10^2 \le \beta \le 10^6$$

However, it must be noted again that values of  $\beta < 10^2$  and  $\beta > 10^6$  are possible.

The damping parameter defined by Equation (3-102) is actually the ratio of the viscous damping coefficient and the critical damping coefficient for the first harmonic, i.e., n = 1. The critical damping coefficient is thus given by

$$c_{cr} = \frac{h}{R} \sqrt{\frac{\rho E}{g}}$$
 (3-103)

Hence for the solutions presented in this report, the damping parameter will be limited to the range of values

$$0 \le \alpha \le 1.0$$

The actual value of  $\alpha$  that should be used in a design situation is not known, and its determination is beyond the scope of the present report. However, as will be shown later, it could be a significant factor in the determination of the true dynamic response of ducts with contained fluid. This aspect of the problem is discussed further in Section VI with regard to the interaction of fluid and duct motions (coupled motion).

The dynamic solutions were nondimensionalized in such a manner as to yield non-dimensional radial deflections  $\bar{w}$  and axial bending moment  $\bar{M}_x$ . These parameters are defined by

$$\overline{W} = \frac{W}{W_0}; \overline{M}_X = \frac{M_X}{M_0}$$
 (3-104)

where

$$w_0 = \frac{pR^2}{Eh}$$
;  $M_0 = \frac{pRh}{\sqrt{12(1-\nu^2)}}$  (3-105)

The spike load is essentially a limiting case of the sinusoidal pressure load but it must be given in terms the radial line load P instead of the pressure p. As a consequence of this fact, the expressions for  $\mathbf{w}_0$  and  $\mathbf{M}_0$  for the spike are given by

$$w_{o_{\mathbf{p}}} = \frac{\mathbf{p}^{4} \sqrt{12 (1 - \nu^{2})}}{\mathbf{E}} \left(\frac{\mathbf{R}}{\mathbf{h}}\right)^{3/2}$$

$$M_{o_{\mathbf{p}}} = 4 \sqrt{\frac{\mathbf{ph}^{1/2} \mathbf{R}^{1/2}}{12 (1 - \nu^{2})}}$$
(3-106)

The hoop and circumferential bending moment stress resultants are given in terms of  $\bar{w}$  and  $\bar{M}_{\bar{w}}$  by (see Equations 3-7 and 3-8).

$$N_{\phi} = \frac{Eh w_{o}}{R} \overline{w}$$

$$M_{\phi} = \nu M_{o} \overline{M}_{x}$$
(3-107)

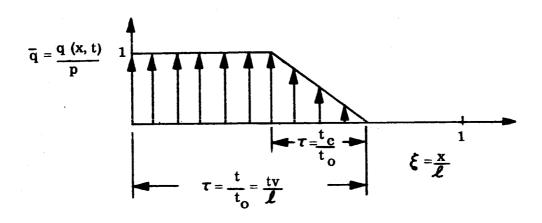

By the suitable combination of the stresses  $\sigma_x$  and  $\sigma_\phi$  obtained from the stress resultants  $M_x$ ,  $M_\phi$  and  $N_\phi$ , the state of biaxial stresses at any point in the duct can be determined. (see Section V-C, Illustrative Application of Design Charts.)

Nondimensional variables introduced with regard to the representation of the ramp and sinusoidal pressure transients are shown in Figure III-12. Other nondimensional variables are introduced as they appear.

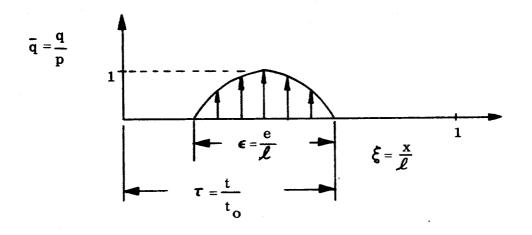

## E. SUMMARY AND SOLUTION OF FINAL GOVERNING EQUATIONS

### 1. Final Governing Equations

Introductions of the nondimensional design parameters and variables discussed in Section III-D into the expressions presented in Section III-C for the dynamic solution of a cylinder of finite length results in the following nondimensional forms for the deflection and bending moment expressions

(a) Ramp

(b) Sinusoid

Figure III-12. Nondimensional Representation of Pressure Wave Shapes

$$\overline{\mathbf{w}} = \sum_{n=1}^{\infty} \mathbf{F}_{n}(\tau) \, \mathbf{W}_{n}(\xi)$$

$$\overline{\mathbf{M}}_{\mathbf{x}} = \frac{1}{\beta} \sum_{n=1}^{\infty} \mathbf{F}_{n}(\tau) \, \frac{\partial^{2} \mathbf{W}_{n}(\xi)}{\partial \xi^{2}}$$
(3-108)

The function  $F_n(\tau)$  is obtained as the solution of the following differential equation which is the nondimensional form of Equation (3-60)

$$\frac{d^2 F_n}{d\tau^2} + 2\overline{\alpha} \frac{dF_n}{d\tau} + \Omega_n^2 F_n = A_n(\tau)$$
(3-109)

where

$$\bar{\alpha} = \alpha \sqrt{\frac{\beta}{2\lambda}}$$

$$\Omega_{n}^{2} = \frac{1}{2\lambda\beta} (\beta^{2} + K_{n}^{4})$$
(3-110)

Note that  $\Omega_n$  is the nondimensional natural frequency. The nondimensional function  $A_n$  ( $\tau$ ) corresponds to the expression on the right hand side of Equation 3-60 and is given by

$$A_{n}(\tau) = \frac{2\beta}{\lambda K_{n}} \int_{0}^{1} \overline{q}(\xi, \tau) W_{n}(\xi) d\xi$$
 (3-111)

where  $\overline{q} = q/p$ , the nondimensional pressure.

The functions  $W_n$  ( $\xi$ ),  $K_n$  and  $K_n$  vary with the prescribed boundary conditions and they are summarized, for the cases treated in this study, as follows. For simple-simple support conditions

$$\begin{array}{lll}
W_{n}(\xi) &= \sin K_{n} \xi \\
\frac{\partial^{2} W_{n}}{\partial \xi^{2}} &= -K_{n}^{2} \sin K_{n} \xi \\
K_{n} &= 2 \\
K_{n} &= n \pi
\end{array}$$
(3-112)

58

and for fixed-fixed support conditions

$$W_{n}(\xi) = \cosh K_{n} \xi - \cos K_{n} \xi - \alpha_{n} \left( \sinh K_{n} \xi - \sin K_{n'} \xi \right)$$

$$\alpha_{n} = \frac{\cos K_{n} - \cosh K_{n}}{\sin K_{n} - \sinh K_{n}}$$

$$K_{n} = 4$$

$$1 = \cos K_{n} \cosh K_{n}$$

$$(3-113)$$

Note that  $K_n$  are the roots of the last expression of Equations 3-113

Substitution of the expressions for the various transient pressure cases defined in Chapter II into Equation 3-111 and integrating results in the function  $A_n$  ( $\tau$ ), the nonhomogenious part of the differential equation, Equation 3-109. The functions obtained for the ramp and sinusoid transient pressures are summarized below for the two boundary conditions under investigation.

# (1) Simple-Simple Supports

(a) Ramp Pressure Form,  $\tau_c \le 1$   $0 \le \tau \le \tau_c \qquad A_n(\tau) = \frac{\beta}{\lambda K_n} \left[ \frac{\tau}{\tau_c} - \frac{1}{K_n \tau_c} \sin K_n \tau \right]$   $\tau_c \le \tau \le 1 \qquad A_n(\tau) = \frac{\beta}{\lambda K_n} \left[ 1 - \frac{1}{K_n \tau_c} \left( \sin K_n \tau - \sin K_n (\tau - \tau_c) \right) \right]$   $1 \le \tau \le 1 + \tau_c \qquad A_n(\tau) = \frac{\beta}{\lambda K_n} \left[ 1 + \frac{1}{K_n \tau_c} \left( \sin K_n (\tau - \tau_c) + \sin K_n (2 - \tau) \right) \right]$   $1 + \tau_c \le \tau \le 2 \qquad A_n(\tau) = \frac{\beta}{\lambda K_n} \left[ 1 - \frac{1}{K_n \tau_c} \left( \sin K_n (2 - \tau + \tau_c) - \sin K_n (2 - \tau) \right) \right]$   $2 \le \tau \le 2 + \tau_c \qquad A_n(\tau) = \frac{-\beta}{\lambda K_n} \left[ \frac{2\tau - 4 - \tau_c}{\tau_c} - \frac{1}{K_n \tau_c} \left( \sin K_n (\tau - 2) - \sin K_n (\tau - 2 - \tau_c) \right) \right]$ 

$$2 + \tau \sum_{c} \leq \tau \leq 3 \qquad A_{n}(\tau) = \frac{-\beta}{\lambda K_{n}} \left[ 1 - \frac{1}{K_{n} \tau_{c}} \left( \sin K_{n}(\tau - 2) - \sin K_{n}(\tau - 2 - \tau_{c}) \right) \right]$$

$$3 \leq \tau \leq 3 + \tau \sum_{c} A_{n}(\tau) = \frac{-\beta}{\lambda K_{n}} \left[ 1 + \frac{1}{K_{n} \tau_{c}} \left( \sin K_{n}(\tau - 2 - \tau_{c}) - \sin K_{n}(4 - \tau) \right) \right]$$

$$3 + \tau \sum_{c} \leq \tau \leq 4 \qquad A_{n}(\tau) = \frac{-\beta}{\lambda K_{n}} \left[ 1 + \frac{1}{K_{n} \tau_{c}} \left( \sin K_{n}(\tau - 4 - \tau_{c}) + \sin K_{n}(4 - \tau) \right) \right]$$

$$4 \leq \tau \leq 4 + \tau_{c} \qquad A_{n}(\tau) = \frac{\beta}{\lambda K_{n}} \left[ \frac{\tau - 4 - \tau_{c}}{\tau_{c}} + \frac{1}{K_{n} \tau_{c}} \left( \sin K_{n}(\tau - 4 - \tau_{c}) \right) \right]$$

$$+ A_{n}(\tau) = \frac{\beta}{\lambda K_{n}} \left[ \frac{\tau - 4 - \tau_{c}}{\tau_{c}} + \frac{1}{K_{n} \tau_{c}} \left( \sin K_{n}(\tau - 4 - \tau_{c}) \right) \right]$$

$$(3-114)$$

## (b) Sinusoidal Pressure Form $\epsilon \leq 1$

For this transient pressure form the expressions obtained for  $A_n(\tau)$  become unbounded when  $n=\frac{1}{\epsilon}$ . Because of this circumstance, the function  $A_n(\tau)$  was evaluated for two cases, i.e., when  $n\neq\frac{1}{\epsilon}$  and when  $n=\frac{1}{\epsilon}$ . For  $n\neq\frac{1}{\epsilon}$ 

$$0 \le \tau \le \epsilon \qquad A_{n}(\tau) = \frac{\beta}{\lambda K_{n}} \left[ \frac{n \epsilon}{1 - \epsilon^{2} n^{2}} \left( \sin K_{n} \tau - n \epsilon \sin \frac{\pi \tau}{\epsilon} \right) \right]$$

$$\epsilon \le \tau \le 1 \qquad A_{n}(\tau) = \frac{\beta}{\lambda K_{n}} \left[ \frac{n \epsilon}{1 - \epsilon^{2} n^{2}} \left( \sin K_{n} \tau + \sin K_{n}(\tau - \epsilon) \right) \right]$$

$$1 \le \tau \le 1 + \epsilon \qquad A_{n}(\tau) = \frac{\beta}{\lambda K_{n}} \left[ \frac{n \epsilon}{1 - \epsilon^{2} n^{2}} \left( \sin K_{n}(\tau - \epsilon) - \sin K_{n}(2 - \tau) \right) \right]$$

$$1 + \epsilon \le \tau \le 2 \qquad A_{n}(\tau) = \frac{\beta}{\lambda K_{n}} \left[ \frac{n \epsilon}{1 - \epsilon^{2} n^{2}} \left( \sin K_{n}(2 - \tau + \epsilon) + \sin K_{n}(2 - \tau) \right) \right]$$

$$2 \le \tau \le 2 + \epsilon \qquad A_{n}(\tau) = \frac{\beta}{\lambda K_{n}} \left[ \frac{n \epsilon}{1 - \epsilon^{2} n^{2}} \left( -\sin K_{n}(2 - \tau + \epsilon) + \sin K_{n}(\tau - 2) \right) \right]$$

$$2 + \epsilon \le \tau \le 3 \qquad A_{n}(\tau) = \frac{\beta}{\lambda K_{n}} \left[ \frac{n \epsilon}{1 - \epsilon^{2} n^{2}} \left( \sin K_{n}(\tau - 2) + \sin K_{n}(\tau - 2 - \epsilon) \right) \right]$$

$$\begin{split} &3 \leq \tau \leq 3 + \epsilon \qquad A_{_{\mathbf{I}}}\left(\tau\right) = \frac{\beta}{\lambda \, \mathsf{K}_{_{\mathbf{I}}}} \, \left[ \frac{\mathsf{n} \, \epsilon}{1 - \epsilon^{\,\, 2} \, \mathsf{n}^{\,2}} \, \left( \sin \mathsf{K}_{_{\mathbf{I}}} \left(\tau - 2 - \epsilon\right) - \sin \mathsf{K}_{_{\mathbf{I}}} \left(4 - \tau\right) \right) \right] \\ &3 + \epsilon \leq \tau \leq 4 \qquad A_{_{\mathbf{I}}}\left(\tau\right) = \frac{-\beta}{\lambda \, \mathsf{K}_{_{\mathbf{I}}}} \, \left[ \frac{\mathsf{n} \, \epsilon}{1 - \epsilon^{\,\, 2} \, \mathsf{n}^{\,2}} \, \left( \sin \mathsf{K}_{_{\mathbf{I}}} \left(4 - \tau\right) + \sin \mathsf{K}_{_{\mathbf{I}}} \left(4 - \tau\right) + \epsilon\right) \right) \right] \\ &4 \leq \tau \leq 4 + \epsilon \qquad A_{_{\mathbf{I}}}\left(\tau\right) = \frac{-\beta}{\lambda \, \mathsf{K}_{_{\mathbf{I}}}} \, \left[ \frac{\mathsf{n} \, \epsilon}{1 - \epsilon^{\,\, 2} \, \mathsf{n}^{\,2}} \, \left( \sin \mathsf{K}_{_{\mathbf{I}}} \left(4 - \tau\right) + \sin \mathsf{K}_{_{\mathbf{I}}} \left(4 - \tau\right) + \epsilon\right) \right) \right] \\ &4 \leq \tau \leq 4 + \epsilon \qquad A_{_{\mathbf{I}}}\left(\tau\right) = \frac{-\beta}{\lambda \, \mathsf{K}_{_{\mathbf{I}}}} \, \left[ \frac{\mathsf{n} \, \epsilon}{1 - \epsilon^{\,\, 2} \, \mathsf{n}^{\,2}} \, \left( \sin \mathsf{K}_{_{\mathbf{I}}} \left(4 - \tau\right) + \epsilon\right) \right) \right] \\ &4 \leq \tau \leq 4 + \epsilon \qquad A_{_{\mathbf{I}}}\left(\tau\right) = \frac{-\beta}{\lambda \, \mathsf{K}_{_{\mathbf{I}}}} \, \left[ \frac{\mathsf{n} \, \epsilon}{1 - \epsilon^{\,\, 2} \, \mathsf{n}^{\,2}} \, \left( \sin \mathsf{K}_{_{\mathbf{I}}} \left(4 - \tau\right) + \sin \mathsf{K}_{_{\mathbf{I}}} \left(4 - \tau\right) \right) \right) \right] \\ &4 \leq \tau \leq 4 + \epsilon \qquad A_{_{\mathbf{I}}}\left(\tau\right) = \frac{-\beta}{2 \, \lambda} \, \left[ \tau \, \cos \pi \, \frac{\tau}{\epsilon} - \frac{\epsilon}{\pi} \sin \pi \, \frac{\tau}{\epsilon} \right] \\ &4 \leq \tau \leq 1 \qquad A_{_{\mathbf{I}}}\left(\tau\right) = \frac{-\beta}{2 \, \lambda} \, \left[ \tau \, \cos \pi \, \frac{\tau}{\epsilon} + \left(\tau - \epsilon\right) \cos \pi \, \frac{\left(\tau - \epsilon\right)}{\epsilon} \right) + \left(\tau - \epsilon\right) \cos \pi \, \frac{\left(\tau - \epsilon\right)}{\epsilon} \right] \\ &2 \leq \tau \leq 1 + \epsilon \qquad A_{_{\mathbf{I}}}\left(\tau\right) = \frac{\beta}{2 \, \lambda} \, \left[ \tau \, \cos \pi \, \frac{\tau}{\epsilon} + \left(\tau - \epsilon\right) \cos \pi \, \frac{\left(\tau - \epsilon\right)}{\epsilon} \right) \cos \pi \, \frac{\left(\tau - 2\right)}{\epsilon} \right] \\ &2 \leq \tau \leq 2 + \epsilon \qquad A_{_{\mathbf{I}}}\left(\tau\right) = \frac{\beta}{2 \, \lambda} \, \left[ \tau \, \cos \pi \, \frac{\left(\tau - \epsilon\right)}{\epsilon} + \left(\tau - 2 - \epsilon\right) \cos \pi \, \frac{\left(\tau - 2\right)}{\epsilon} \right] \\ &2 \leq \tau \leq 3 \qquad A_{_{\mathbf{I}}}\left(\tau\right) = \frac{\beta}{2 \, \lambda} \, \left[ \tau \, \cos \pi \, \frac{\left(\tau - 2\right)}{\epsilon} + \left(\tau - 2 - \epsilon\right) \cos \pi \, \frac{\left(\tau - 2\right)}{\epsilon} \right) \\ &3 \leq \tau \leq 3 + \epsilon \qquad A_{_{\mathbf{I}}}\left(\tau\right) = \frac{\beta}{2 \, \lambda} \, \left[ \tau \, \cos \pi \, \frac{\left(\tau - 2\right)}{\epsilon} + \left(\tau - 2 - \epsilon\right) \cos \pi \, \frac{\left(\tau - 2\right)}{\epsilon} \right) \\ &3 \leq \tau \leq 4 \qquad A_{_{\mathbf{I}}}\left(\tau\right) = \frac{\beta}{2 \, \lambda} \, \left[ \left(4 - \tau\right) \cos \pi \, \frac{\left(4 - \tau\right)}{\epsilon} + \left(4 - \tau\right) + \epsilon\right) \cos \pi \, \frac{\left(4 - \tau\right)}{\epsilon} \right] \\ &4 \leq \tau \leq 4 + \epsilon \qquad A_{_{\mathbf{I}}}\left(\tau\right) = \frac{\beta}{2 \, \lambda} \, \left[ \left(4 - \tau\right) \cos \pi \, \frac{\left(4 - \tau\right)}{\epsilon} + \left(4 - \tau\right) + \epsilon\right) \cos \pi \, \frac{\left(4 - \tau\right)}{\epsilon} \right] \\ &4 \leq \tau \leq 4 + \epsilon \qquad A_{_{\mathbf{I}}}\left(\tau\right) = \frac{\beta}{2 \, \lambda} \, \left[ \left(4 - \tau\right) \cos \pi \, \frac{\left(4 - \tau\right)}{\epsilon} + \left(4 - \tau\right) + \epsilon\right) \cos \pi \, \frac{\left(4 - \tau\right)}{\epsilon} \right] \\ &4 \leq \tau \leq 4 + \epsilon \qquad A_{_{\mathbf{I}}}\left(\tau\right) = \frac{\beta}{2 \, \lambda} \,$$

(3-116)

# (2) Clamped - Clamped Supports

(a) Ramp Pressure Form  $\tau_c \le 1$

## (b) Sinusoidal Pressure Form $\epsilon \leq 1$

As was the situation for the case of simple-simple supports, there are two sets of functions required for  $A_n(\tau)$ , i.e., for  $K_n = \frac{\pi}{\epsilon}$  and  $K_n \neq \frac{\pi}{\epsilon}$ . For  $K_n = \frac{\pi}{\epsilon}$  we have

$$0 \le \tau \le \epsilon \qquad A_{n}(\tau) = \frac{-\beta \epsilon}{2 \lambda \pi} \left[ \cos \frac{\pi \tau}{\epsilon} - \cosh \frac{\pi \tau}{\epsilon} + \frac{\tau \pi}{\epsilon} \sin \frac{\pi \tau}{\epsilon} \right.$$

$$-\alpha_{n} \left( 2 \sin \frac{\pi \tau}{\epsilon} - \sinh \frac{\pi \tau}{\epsilon} - \frac{\pi \tau}{\epsilon} \cos \frac{\pi \tau}{\epsilon} \right) \right]$$

$$\epsilon \le \tau \le 1 \qquad A_{n}(\tau) = \frac{\beta \epsilon}{2 \lambda \pi} \left[ \cosh \frac{\pi \tau}{\epsilon} + \cosh \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi \tau}{\epsilon} \sin \frac{\pi \tau}{\epsilon} \right.$$

$$+ \frac{\pi (\tau - \epsilon)}{\epsilon} \sin \frac{\pi (\tau - \epsilon)}{\epsilon}$$

$$-\alpha_{n} \left( \sinh \frac{\pi \tau}{\epsilon} + \sinh \frac{\pi (\tau - \epsilon)}{\epsilon} + \frac{\pi \tau}{\epsilon} \cos \frac{\pi \tau}{\epsilon} \right.$$

$$+ \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} \right) \right]$$

$$1 \le \tau \le 1 + \epsilon \qquad A_{n}(\tau) = \frac{\beta \epsilon}{2 \lambda \pi} \left[ 2 \cos \frac{\pi (\tau - 1)}{\epsilon} \cosh \frac{\pi}{\epsilon} + \cosh \frac{\pi (\tau - \epsilon)}{\epsilon} \right.$$

$$- \cosh \frac{\pi (2 - \tau)}{\epsilon} - \frac{2\pi}{\epsilon} \cos \frac{\pi (\tau - 1)}{\epsilon} \sin \frac{\pi}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} \right.$$

$$\sin \frac{\pi (\tau - \epsilon)}{\epsilon}$$

$$+ \frac{\pi (2 - \tau)}{\epsilon} \sin \frac{\pi (2 - \tau)}{\epsilon} - \alpha_{n} \left( 2 \cos \frac{\pi (\tau - 1)}{\epsilon} \right) \sinh \frac{\pi}{\epsilon}$$

$$+ \sinh \frac{\pi (\tau - \epsilon)}{\epsilon} - \sinh \frac{\pi (2 - \tau)}{\epsilon} + \frac{2\pi}{\epsilon} \cos \frac{\pi (\tau - 1)}{\epsilon} \cos \frac{\pi}{\epsilon}$$

$$+ \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} - \sinh \frac{\pi (2 - \tau)}{\epsilon} \cos \frac{\pi (2 - \tau)}{\epsilon} \right)$$

$$+ \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} - \sinh \frac{\pi (2 - \tau)}{\epsilon} \cos \frac{\pi (2 - \tau)}{\epsilon} \right)$$

$$+ \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} + \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} + \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{\pi (\tau - \epsilon)}{\epsilon} \cos \frac{\pi (\tau - \epsilon)}{\epsilon} - \frac{$$

$$\left. + A_n(\tau) \right|_0 \le \tau \le \epsilon \qquad (3-119)$$

The above expressions for  $A_n$  ( $\tau$ ) are written for the number of traverses required to completely represent the history of transient pressures. It should be noted that the last term in the last expression is a repeat of the first expression for the first time interval. Thus, the expressions for  $A_n$  ( $\tau$ ) are employed cyclically as time progresses.

## 2. Adaptation to Automatic Computation

As explained in Section II, the transient pressure forms under consideration continually traverse the cylinder from one end to the other. Algebraic expressions which yield the deflections and stresses at any time in the sequence of transient pressure traverses can be derived by the procedure employed for the sample solutions of Section III-C. However, depending on the type of transient pressure, the size and complexity of the algebraic expressions for the response solution increases with each traverse and soon becomes unwieldy. After examination of the various techniques that could be employed to overcome this problem, it was thought appropriate to adopt a conventional numerical method of solution which could be readily programmed for use on the digital computer. All the analytics pertinent to such a method of solution were presented in the previous section.

The solution of Equation 3-109 can be efficiently obtained by the predictor corrector technique of numerical integration which is explained in Reference 3-5.

This technique was used as the basis for a general purpose computer program which was programmed to give results for the ramp and sinusoidal transient pressure forms. As explained above, in the limit, these cases reduce respectively to the step and spike pressure types. The general purpose program is presented, together with illustrative problems as a users manual in Volume II of this report.

## 3. Summary of Solutions

As stated previously, obtaining expressions for the response of cylinders subjected to many traverses of the pressure transient is prohibitive and consequently it is best to obtain design data by numerical integration of the separated differential equation, Equation 3-109. However, under certain circumstances only the first traverse

of the pressure transient is required. In addition, such solutions which are less costly to run on digital equipment, could be used to check the numerically obtained solution and to generate design data, in spite of its limitation.

Design data presented in this document are valid for only the first traverse of the pressure transient under consideration. Expressions used to compute the data are summarized in this section. However, where it is convenient, the dynamic solutions were extended beyond the first traverse.

Since the solution is given by Equation 3-108, only expressions for the time dependent function  $F_n$  ( $\tau$ ) need be documented. In general, the expression for  $F_n$  ( $\tau$ ) for all cases treated will be of the form

$$F_{n}(\tau) = \bar{a}_{n} \left[ e^{-\bar{\alpha}\tau} \left( A_{in} \cos \bar{\Omega}_{n} \tau + B_{in} \sin \bar{\Omega}_{n} \tau \right) + F_{p_{in}}(\tau) \right]$$
(3-120)

where  $\overline{a}_n$ ,  $A_{in}$ ,  $B_{in}$  and  $F_{p_{in}}$  ( $\tau$ ) depend on the form of the pressure transient under consideration and are summarized below. The subscript "i" is introduced to identify the time interval where necessary. The damped nondimensional natural frequency  $\overline{\Omega}_n$  is given by

$$\tilde{\Omega}_n^2 = \Omega_n^2 - \bar{\alpha}^2 \tag{3-121}$$

(a) Spike Pressure, Simple-Simple Edge Conditions  $0 \le \tau$ 

$$\begin{array}{lll}
\mathbf{F}_{\mathbf{p}_{\mathbf{n}}}(\tau) &= \mathbf{C}_{\mathbf{n}} \sin \mathbf{n} \, \boldsymbol{\pi} + \mathbf{D}_{\mathbf{n}} \cos \mathbf{n} \, \boldsymbol{\pi} \, \boldsymbol{\tau} \\
\boldsymbol{\beta}^{1/2} \\
\bar{\mathbf{a}}_{\mathbf{n}} &= \frac{\boldsymbol{\beta}^{1/2}}{\lambda \left[ (\Omega_{\mathbf{n}}^{2} - \mathbf{n}^{2} \boldsymbol{\pi}^{2})^{2} + (2 \, \mathbf{n} \boldsymbol{\pi} \bar{\mathbf{a}})^{2} \right]} \\
\mathbf{A}_{\mathbf{n}} &= 2 \, \mathbf{n} \, \boldsymbol{\pi} \bar{\mathbf{a}} \\

#### IV. SUMMARY OF RESULTS

#### A. TYPICAL DYNAMICAL RESPONSE SOLUTIONS

The elastic dynamic response solutions presented in this report will yield the complete history of deflection profiles and stress fields as a function of the design parameters discussed in Section III-D. Each set of design parameters represents a specific time dependent design situation and consequently, as this study has clearly indicated, must be investigated in detail if a thorough understanding and analysis of the dynamic response of the shell is to be obtained. Such an exhaustive investigation, although feasible for a particular design situation, is not feasible for the range of values of the design parameters discussed in Section III-D. Hence, it is the intent of this section to present only sufficient detail which reveals the significant characteristics of the response of cylinders to transient pressures. This information is then used as the basis for the method adopted for the development of design charts.

### 1. Infinite Length Shell

Typical deflection profiles and bending moment distributions are presented for the shell of infinite length subjected to a traveling pressure spike in Figures IV-1 through IV-4. Damping was neglected ( $\alpha=0$ ). Two distinct deflection profiles are obtained depending on whether the speed parameter,  $\lambda$ , is greater or less than one. When  $\lambda < 1$  the traveling deflection profile appears as a damped sinusoid that is symmetrical with respect to  $\xi=0$  as shown in Figure IV-1. The maximum deflection occurs at  $\xi=0$  and increases with an increase in  $\lambda$ .

When  $\lambda > 1$ , the deflection profile is sinusoidal as shown in Figure IV-2. Deflections and wave lengths behind the traveling spike are larger than those in front of the spike. In addition, as a result of the oscillatory character of the deflection curve about  $\tilde{\mathbf{w}} = 0$ , maximum negative and positive deflections of equal magnitude are experienced. The maximum deflections decrease with an increase in  $\lambda$ . As  $\lambda$  approaches one from either direction a critical condition is approached which is characterized by unbounded deflections.

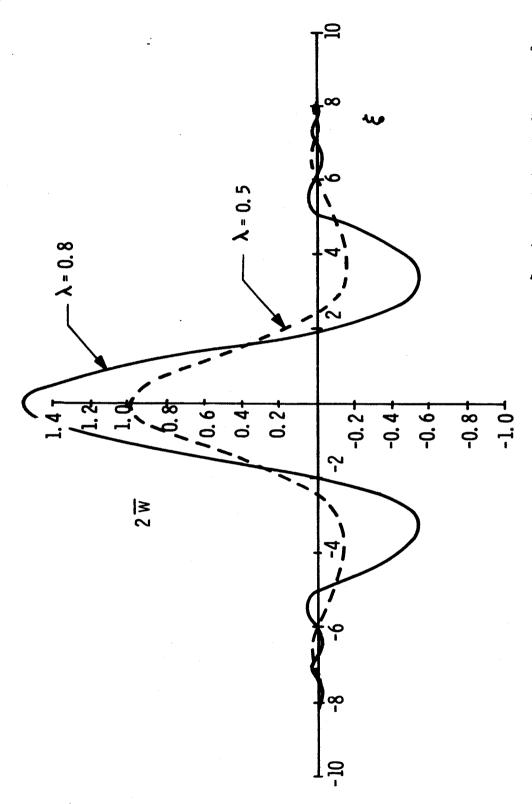

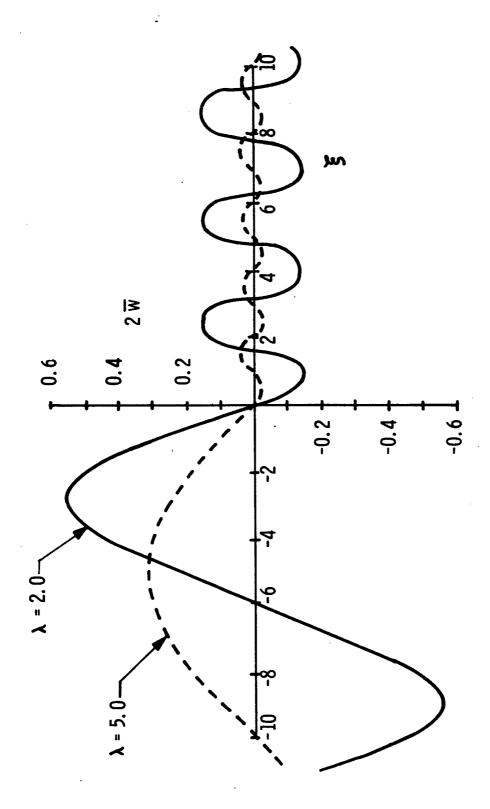

Figure IV-1. Infinite Length Shell, Spike Pressure, Deflection vs  $\xi$ ,  $\lambda < 1$  (Subcritical),

(Supercritical),  $\alpha = 0$ Figure IV-2. Infinite Length Shell, Spike Pressure, Deflection vs ξ, λ > Ι

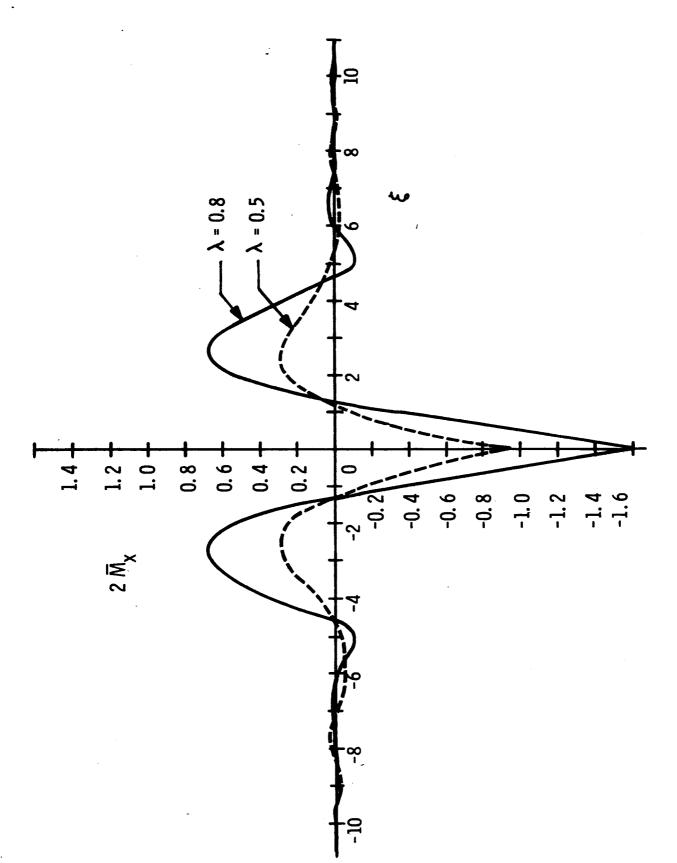

Figure IV-3. Infinite Length Shell, Spike Pressure, Bending Moment vs.  $\xi$ ,  $\lambda < l$  (Subcritical),  $\alpha = 0$ 

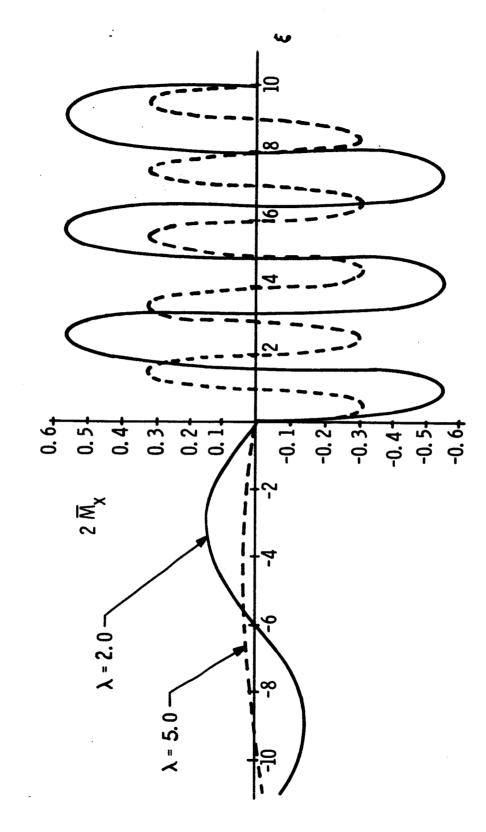

Figure IV-4. Infinite Length Shell, Spike Pressure, Bending Moment vs  $\xi$ ,  $\lambda > 1$  (Supercritical),  $\alpha = 0$ 

For  $\lambda$  < 1, the maximum bending moment is located at  $\xi$  = 0 and increases with an increase in  $\lambda$  as shown in Figure IV-3. The maximum bending moment for  $\lambda$  > 1 occurs in front of the pressure spike and decreases with an increase in  $\lambda$  as shown in Figure IV-4.

Plots of the maximum deflection,  $\overline{w}_{max}$ , and the maximum bending moment,  $\overline{M}_{X_{max}}$  as a function of the speed parameter,  $\lambda$ , are shown in Figures IV-5 and IV-6. The curves in these figures will yield the maximum hoop and bending stresses (see Equation 3-106, 3-107). For  $\lambda$  < 1, the maximum hoop and bending stresses act at the same point,  $\xi$  = 0, and therefore this data is sufficient for design purposes. However, for  $\lambda$  > 1, the maximum deflection does not occur at the same location as the maximum bending stress. Since for design purposes, a complete knowledge of the state of stress at a point is desirable, the deflections and bending moments present at the respective maximum bending moment and deflection locations were determined and presented in Figures IV-7 and IV-8.

Typical deflection profiles for the step pressure case are shown in Figure IV-9 (see Reference 3.3). It should be noted that the deflection profile is in the shape of waves which oscillate about  $\bar{\mathbf{w}} = 0$  for  $\xi > 1$  and oscillate about  $\bar{\mathbf{w}} = 1$  for  $\xi < 1$ . For  $\lambda < 1$  a point possessing both the maximum deflection and bending stress occurs behind the pressure wave front. For  $\lambda > 1$ , the maximum deflection occurs behind the pressure wave front whereas maximum bending moments occur at and in front of the pressure wave front.

Maximum deflections and bending stresses for the step pressure are given in Figures IV-10 and IV-11. It is significant to note that for  $\lambda > 1$ , the maximum deflection never decreases below  $\bar{w}_{max} = 2$ .

Solutions obtained for the infinite shell correspond to the steady-state solution and their applicability to practical shells of finite length must be ascertained. The practical significance of solutions for the infinitely long shell is discussed in Section IV-B.

### 2. Finite Length Duct

## a. Convergence of Solution

Since the elastic dynamic response solutions for the finite length cylinders are in the form of an infinite series, it is necessary to determine the number of terms, N, required for convergence of the series solution for each combination of the parameters  $\lambda$  and  $\beta$ .

Determination of the number of terms in the series solution required to yield adequate accuracy was accomplished with the aid of curves such as shown in Figures IV-12 through IV-16. These curves, which reveal the convergence characteristics of the series solutions, give the variations of the radial deflection,  $\bar{\mathbf{w}}$ , and bending moment,  $\bar{\mathbf{M}}_{\mathbf{X}}$ , as a function of the total number of terms, N, considered in the series solution. The specific curves shown were drawn for the spike transient pressure case which was studied in some detail because it is believed to represent the most severe situation from a convergence standpoint.

Figures IV-12 through IV-15 were drawn for  $\lambda=2$ , values of  $\beta$  from  $10^2$  to  $10^5$ , time  $\tau=0.5$ ,  $\alpha=0$ , and location  $\xi=0.5$ . The curves in Figure IV-16 were obtained for  $\beta=10^5$ ,  $\lambda=4$ ,  $\tau=0.5$ ,  $\alpha=0$ , and  $\xi=0.5$ . It is evident from a study of these results that the number of terms, N, required to attain convergence increases with increase in  $\beta$  or  $\lambda$ . In addition, all of these curves exhibit two peaks which occur before the series converges. Hence, a knowledge of the location of these peaks will give a lower bound to the number of terms which must be taken in the series solution and is discussed below.

The location of the peaks in the convergence curves discussed above is related to the resonance characteristics of the shell. At resonance, we have the condition (see Equation (3-71))

$$k_{n}^{2} v - \omega_{n} = 0$$
 (4-1)

## a) Deflection

 $N \sim Number of Terms in Series Solution$ 

# b) Bending Moment

Figure IV-16. Variation of Deflection and Bending Moment with the Number of Terms in Series Solution, Spike Pressure, Simple Supports

Using Equation 3-57 to eliminate the natural frequency  $\omega_n$ , results in

$$k_n^2 v^2 = \frac{D}{m \ell^4} \left( \frac{Eh \ell^4}{DR^2} + k_n^4 \ell^4 \right)$$
 (4-2)

Introduction of the nondimensional parameters yields

$$\frac{\beta^2}{K_n} + 1 = \frac{2\lambda\beta}{K_n^2}$$
 (4-3)

Since as n increases,  $K_n$  for the clamped support condition approaches n  $\pi$  which is equal to  $K_n$  for the simple support condition, the above expression can be in general written as

$$2\lambda = \frac{\beta}{n^2 \pi^2} + \frac{n^2 \pi^2}{\beta} \tag{4-4}$$

The relationship between  $\frac{\beta}{n^2 \pi^2}$  and  $\lambda$  as given by this expression is shown in Figure IV-17. Note that a resonance condition for  $\lambda < 1$  does not exist but a resonance condition exists for each value of n which is independent of the form of the pressure transient. Thus, for a given mode, n, a combination of  $\beta$  and  $\lambda$  values can be determined which will excite that mode. If on the other hand a combination of  $\beta$  and  $\lambda$  values are given, it is unlikely that resonance will occur since n is an integer. However, for a given combination of  $\beta$  and  $\lambda$  values, two values of n can be obtained from Figure IV-17 or Equation 4-4 which are not, in general, integers. It appears that the values of n so determined locate the vicinity of the peak values in the convergence plots and the total number of terms, N, taken in the series solution must exceed these computed values of n.

As an aid in determining the value of n which represents a lower bound for N, Figure IV-18 was prepared. This figure was computed from Equation 4-4 and gives the larger critical harmonic number, n as a function of  $\beta$  and  $\lambda$ . The critical harmonic number is defined as the mode number which gives resonance for a given combination of  $\beta$  and  $\lambda$ . The tick marks on the horizontal axis in Figures IV-12 through IV-16 indicate the nearest critical harmonic number for the specified combinations of  $\beta$  and  $\lambda$ .

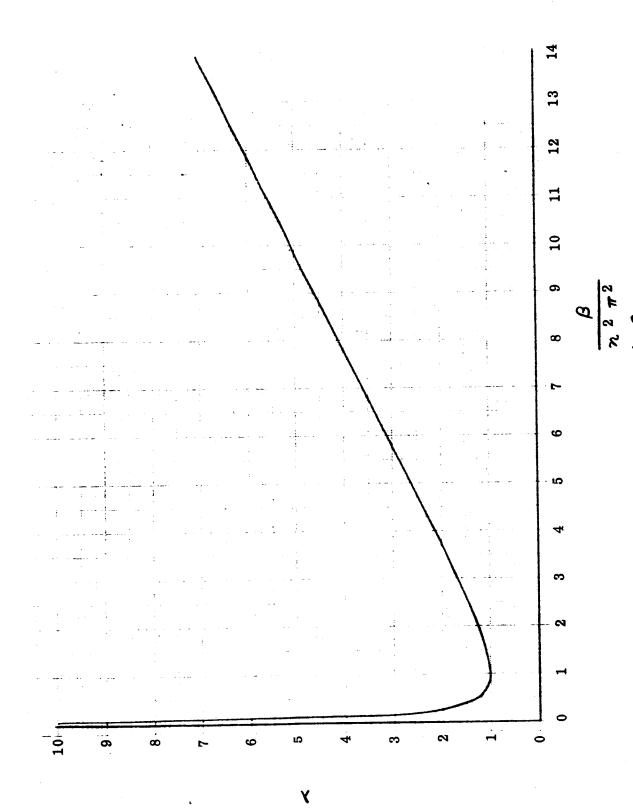

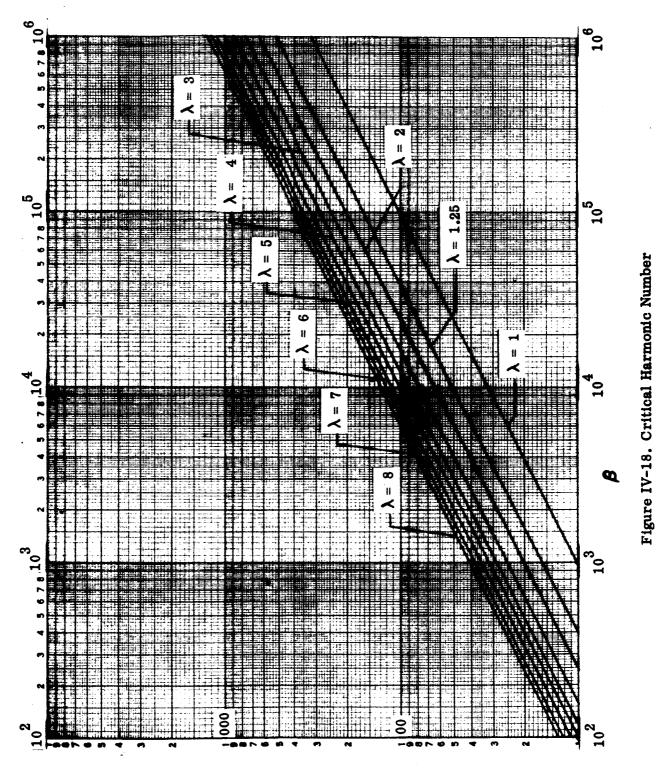

Figure IV-17. Relationship Between  $\lambda, \beta$ , and  $\pi$  for Resonance

N<sub>cr</sub> Critical Harmonic

For  $\lambda$  < 1 the series solution obtained for the spike pressure and simple supports converges in a manner as shown in Figure IV-19. The variation of deflection and bending moment with N for various values of  $\beta$  are indicated in this figure. The speed parameter was taken to be very small, i.e.,  $\lambda$  = 0.001, so that the results could be compared with the exact solution given in Reference 4-1 for an infinite shell subjected to a static ring load. These results indicate that the series solution is correct for small values of  $\lambda$ . Evidently a relatively large number of terms must be taken in the series solution to obtain accurate values for the bending moment.

Results of this study of convergence of the series solution indicates that (as a consequence of the uniformity of the convergence characteristics above a known value of N), development of a convergence criterion for use in a computer program is possible. (see Vol. II). However, for completeness, the convergence characteristics of the remaining solutions should be studies further.

#### b. Deflection Profiles and Stress Distributions

There is no simple, analytical procedure by which the maximum deflection or bending moment can be determined from the series solutions presented in this report. Consequently, such a determination must be obtained by an examination of computed time dependent deflection profiles and stress distributions. Typical data of this type are presented here.

Typical deflection profiles are presented for the step pressure with  $\lambda=2$  and  $\beta=10^4$  at various times in Figure IV-20. Dynamic response results as illustrated in these figures indicate that with the exception of regions near the simply supported cylinder edges, practically all points of the duct experience comparable stress levels during the course of travel of the step pressure. It is of importance to note that the deflection profiles for  $\tau=0.2$  and 0.5 are similar to that given, for the infinite length shell subjected to a step pressure, in Figure IV-9.

The variation with time of the deflection and bending moment at  $\xi=0.5$  for the above case is shown in Figure IV-21. Data of this type are used to obtain design charts discussed in the next section.

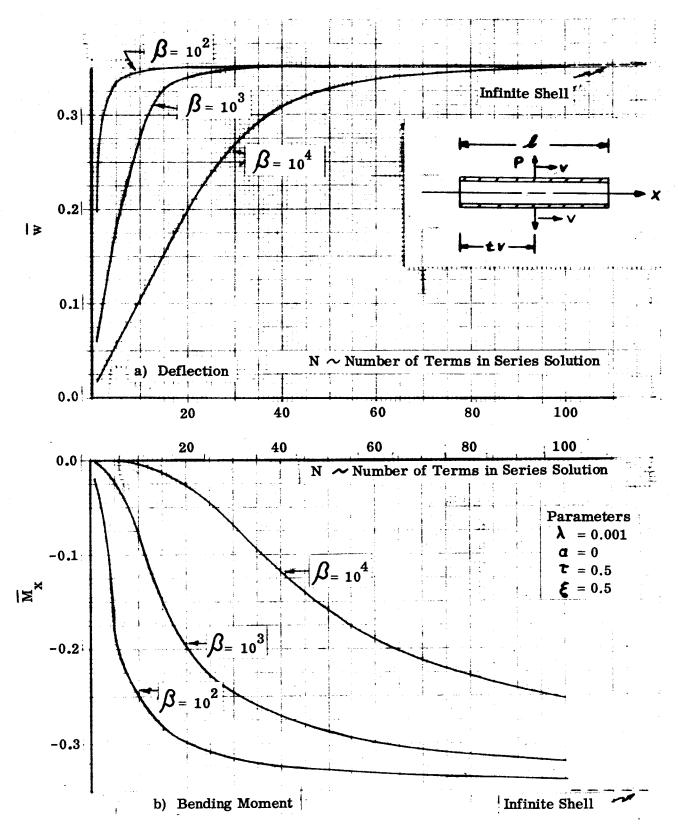

Figure IV-19. Variation of Deflection and Bending Moment With the Number of Terms in Series Solution, Spike Pressure, Simple Supports

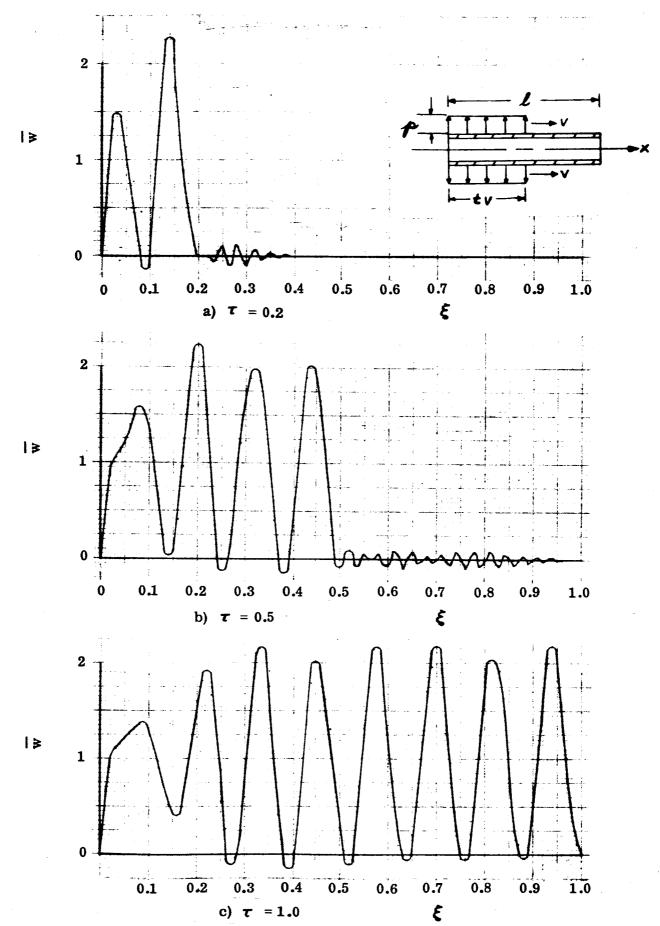

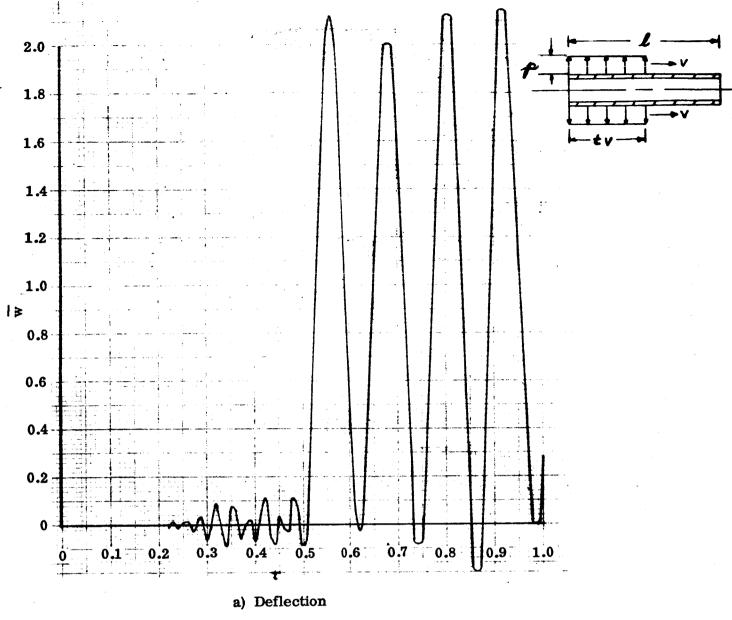

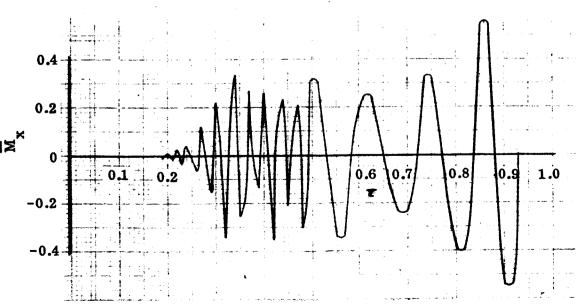

Figure IV-20. Deflection Profiles, Step Pressure, Simple Supports  $\lambda = 2$ ,  $\beta = 10^4$ ,  $\alpha = 0$ , N = 100

b) Bending Moment

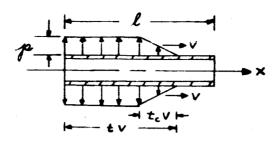

Figure IV-21. Typical Deflection and Bending Moment Variation with Time at  $\xi = 0.5$ , Step Pressure, Simple Supports,  $\lambda = 2$ ,  $\beta = 10^4$ ,  $\alpha = 0$ 

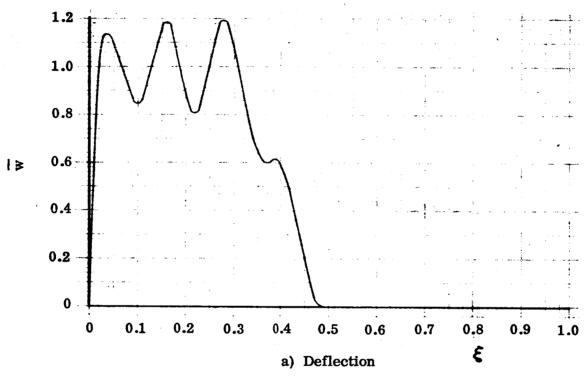

A typical deflection profile for the ramp transient pressure at time  $\tau=0.5$  is shown in Figure IV-22, and typical deflection and bending moment variations with time at location  $\xi=0.5$  are shown in Figure IV-23. These dynamic response results for the cylinder when subjected to a traveling ramp pressure are for a non-dimensional valve closure time at  $\tau_c=0.2$  and design parameter value of  $\lambda=2, \beta=10^4$ ,

 $\alpha = 0$ . The design parameters selected for the ramp pressure are the same used to illustrate cylinder dynamic response to a step pressure presented in Figures IV-20 and IV-21. A comparison of the above typical results obtained for the step and ramp transient pressures reveals that a significant reduction in stress level occurs with the introduction of a valve closure time. It should be noted that practically all points of the duct will experience similar time dependent stress variations and consequently are subject to failure by fatigue.

The history of deflection profiles obtained for the simply supported shell of finite length subjected to a pressure spike is shown in Figures IV-24 through IV-26. Results are shown for  $\beta$  = 10 and various values of  $\lambda$  from 0.5 to 5. Two traverses of the duct are considered. These figures clearly indicate the effects of shell edge supports on dynamic response of a relatively short duct.

Additional typical dynamic response curves are presented in Volume II of this report.

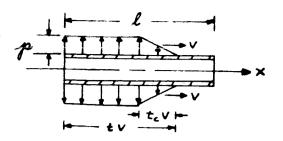

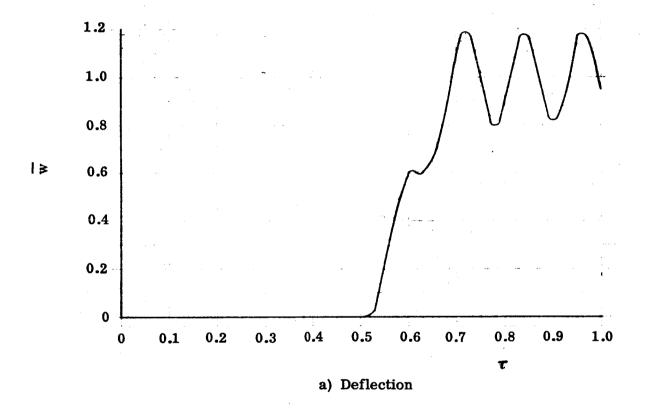

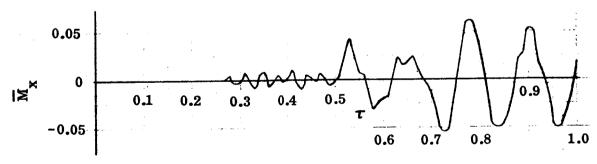

b) Bending Moment Figure IV-22. Typical Deflection and Bending Moment Variation with Position at  $\tau=0.5$ , Ramp Pressure, Simple Supports,  $\lambda=2$ ,  $\beta=10^4$ ,  $\alpha=0$ ,  $\tau_c=0.2$

### B. SIGNIFICANCE OF SOLUTION FOR INFINITE DUCT

Since in reality all ducts are of finite length, the question arises as to the practical applicability of dynamic solutions obtained for the infinite duct. The closed form solution derived for the infinite shell corresponds to a steady state solution whereas the series solution for the shell of finite length is a more general solution which will yield both the transient and steady state response of the duct. Consequently, it is logical to assume that, if boundary effects were negligible, the response of relatively long ducts is similar to that determined for the infinite duct, i.e., for ducts greater than a certain length, the response of the finite shell is approximately that of the infinite shell.

Comparison of results obtained for the shell of finite length with that for the infinite shell indicate that the maximum stresses and deflections for the finite shell are similar if not identical to that of the infinite shell. This observation is clearly indicated by the design charts presented in Section V. The design charts include both the results for the infinite shell and finite length. Evidently in some ranges of the design parameter, the difference in response is negligible as is the case for the spike pressure for  $\lambda < 1$  as shown in Figure V-1. However, in general, the difference in response can be quite significant as indicated for example in Figure V-1, for  $\lambda > 1$ .

In order that the finite length shell be at all comparable to the infinite shell, the length of the shell must be at least greater than the wave length of the deflection profile of the infinite shell. The wave length as a function of the speed parameter is given in Reference 3-3.

If we let the wave length equal  $\mathcal{A}_{w}$  (inches), and, in consistency with the length parameter, define the non-dimensional wave length as

$$\beta_{w} = \frac{{\int_{w}^{2}}}{Rh} \sqrt{12 (1-\nu^{2})} = \gamma^{2} / w^{2} = \bar{\xi}^{2}$$

where  $\overline{\xi}_{\rm w}$  is the wave length given in Reference 3-2, then the wave length versus speed parameter can be shown to be given by Figure IV-27. This curve indicates for example that if  $\lambda = 1.5$  then  $\beta_{\rm w} \approx 100$  and consequently in order that the finite length shell solution be at all comparable to the infinite length shell, the length parameter of the finite length shell must be greater than 100.

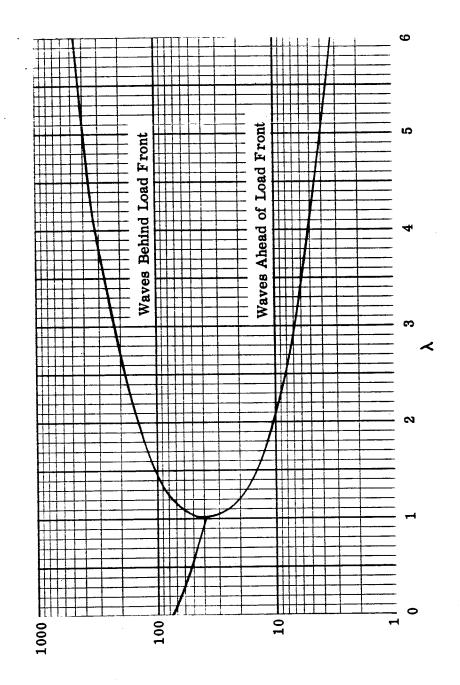

Figure IV-27. Wave Length versus Speed Parameter,  $\lambda$ 

In general, from this portion of the study it appears that solutions obtained for the infinite duct can be used to a limited extent to approximate the response of relatively long ducts. However, this aspect of the subject requires additional study.

## C. SIGNIFICANCE OF DAMPING

Although the dynamic response solutions presented in this report contain the effects of viscous damping, there is no method available for predicting the magnitude of the viscous damping coefficient required for a particular case. Consequently only the significance of damping is investigated.

Typical deflection and bending moment dynamic response curves which include damping for a step pressure are presented in Figures IV-28 and IV-29. These curves are comparable with that of Figure IV-21 which does not include the effects of damping. Comparison of the dynamic response curves in these three figures reveals that there is a significantly large decrease in maximum stress levels when the damping parameter is increased from  $\alpha = 0$  to  $\alpha = 0.1$ , but the decrease in stress level when going from  $\alpha = 0.1$  to  $\alpha = 0.2$  is small.

The influence of damping on the maximum deflection and bending stresses was determined for the traveling spike load and the results indicate that damping effects can be quite significant in reducing deflection and stress levels.

It is concluded from this portion of the study that damping can be quite significant and should be investigated further.

## D. SIGNIFICANCE OF SHEAR AND ROTATORY INERTIA

The theory upon which the present study is based neglects the effects of local shear deformations and rotatory inertia. To determine the significance of shear deformations and rotatory inertia with regard to the dynamic response of cylinders to traveling transient pressures, a solution to the basic shell equations which include the effects of shear deformations and rotatory inertia was obtained and documented in Reference 3-1.

Typical deflection and bending moment dynamic response curves were obtained with the shear theory of Reference 3-1 for traveling step pressure and are compared in

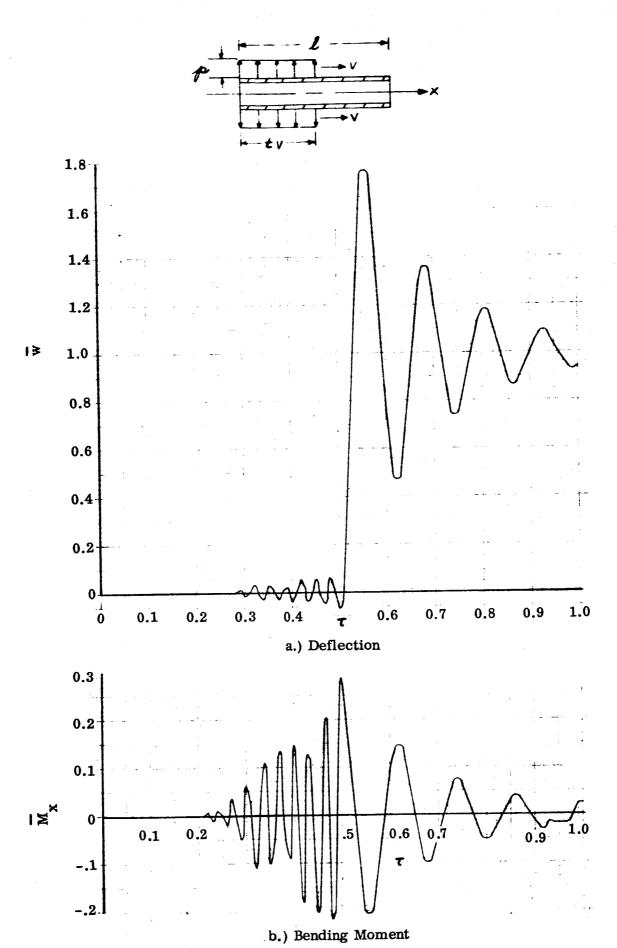

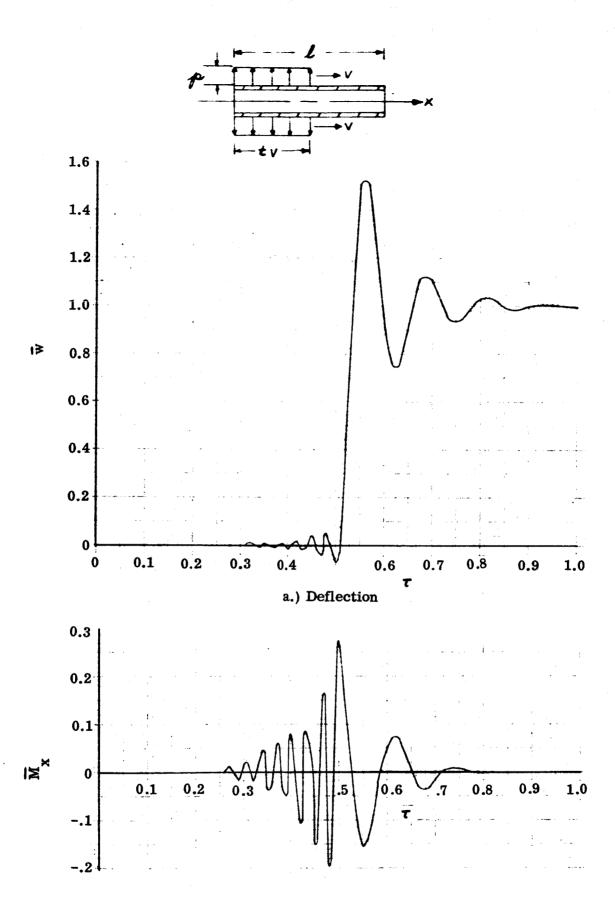

Figure IV-28. Typical Deflection and Bending Moment Variation With Time At  $\xi = .5$ , With Damping a = .1, Step Pressure, Simple Supports,  $\lambda = 2$ ,  $\beta = 10^4$ , N = 100

b.) Bending Moment

Figure IV-29. Typical Deflection and Bending Moment Variation With Time At  $\xi$  = .5, With Damping  $\alpha$  = .2, Step Pressure, Simple Supports,  $\lambda$  = 2,  $\beta$ = 10<sup>4</sup>, N = 100

Figures IV-30 and IV-31 with curves obtained with the theory presented in this report. From an examination of this comparison it is evident that for the design parameter selected, there is little difference in the deflections (see Figure IV-30). But, from an examination of the bending moment results given in Figure IV-31 it appears that shear deformation effects may be of significance. In general, from this portion of the study it may be concluded that for the range of values of design parameter considered in this report, shear and rotating inertia effects can be neglected without introducing significant errors. This subject is discussed further in Section VI-B.

#### V. DESIGN DATA

#### A. METHOD USED TO DETERMINE MAXIMUM STRESSES:

Based on the dynamic response data discussed in Section IV, an approximate but realistic approach to the development of design charts was followed. First based on the convergence characteristics of the series solution, values of N were selected for each combination of  $\beta$  and  $\lambda$  values.

Deflections and bending moments were then determined as a function of time at three locations  $\xi=0.45$ , 0.50 and 0.55 such as shown in Figures IV-21 and IV-23 for  $\xi=0.5$ . Maximum deflections and bending moments were then extracted from this data and design charts prepared.

For cylinders with fixed-fixed boundary conditions, bending moments at both supports were first determined as a function of time, the maximum value was then extracted and separate design charts prepared.

#### B. PRESENTATION OF DESIGN CHARTS

Maximum deflections and bending moments are presented in Figures V-1 through V-26. All the data used to prepare the design charts are summarized in tables which follow the pertinent design charts. These tables also contain the corresponding deflections and bending moments which occur at the points of maximum deflection and bending moment. Also included in the tables are the number of terms, N, taken in the series solution used to generate the design data.

For purposes of aiding in the rapid location of a desired design chart, the following master table was prepared.

MASTER TABLE

# C. ILLUSTRATIVE APPLICATION OF DESIGN CHARTS

As an illustration of the application of the design charts and tables presented in Section V-B, consideration is given to a simply supported circular cylinder subjected to a step type pressure transient. The following cylinder dimensions and material properties are assumed.

R = radius = 10 inches

h = wall thickness = 0.090 inches

l = length = 450 inches

 $\rho$  = weight density = 0.29 lb/in.<sup>3</sup>

E = Young's Modulus =  $29.2 \times 10^6$  psi

 $\nu$  = Poisson's Ratio = 0.3

The speed of the pressure transient front can be assumed equal to the speed of sound of the contained fluid or more realistically approximated by the following expression given in Reference 2-1.

$$v = \sqrt{\frac{\frac{Kg}{\rho_f}}{1 + \frac{K2R}{Eh}}}$$
 (5-1)

where

K = Bulk Modulus of fluid

 $\rho_{f}$  = Mass density of fluid

If the Bulk Modulus and specific gravity of the fluid are assumed respectively as  $1.38 \times 10^5$  psi and 1.142, then the velocity of the pressure transient front given by Equation (5-1) is

$$v = 2,140$$
 ft/sec

Note that the speed of sound for the fluid of the problem assumed is  $a_f = \sqrt{K/\rho_f} = 2,980$  ft/sec and a comparison of this latter speed with that of 2,140 ft/sec computed above indicates that the duct is relatively elastic.

The speed design parameter,  $\lambda$  , as determined from Equation (3-100) for v=2,140 ft/sec is

$$\lambda = \frac{\rho RV^2}{2hE g} \sqrt{12 (1-\nu^2)} = 3.1$$

The length design parameter,  $oldsymbol{eta}$  , given by Equation (3-101), is

$$\beta = \frac{2^2}{Rh} \sqrt{12 (1-\nu^2)} = 7.4 \times 10^5$$

If damping effects are assumed negligible, i.e.  $\alpha = 0$  (see Equation 3-102), then the nondimensional maximum deflection and bending moment as obtained from Figure V-4 is

$$\overline{w}_{max} = 2.1, \overline{M}_{max} = 0.33$$

These maximum values do not occur, in general, at the same time or locations. The corresponding bending moment and deflection as presented in Table 4 are, for this problem, approximately:

$$\overline{w}_{cor.} = 0.0464, \overline{M}_{xcor.} = 0.3027$$

The stresses  $\sigma_{\phi}$  and  $\sigma_{x}$  in the hoop and axial directions respectively can now be determined by the following well-known expressions:

$$\sigma_{\phi} = \frac{N_{\phi}}{h} \pm \frac{\nu M_{x}^{6}}{h^{2}}, \quad \sigma_{x} = \frac{M_{x}^{6}}{h^{2}}$$
 (5-2)

Or, in terms of the nondimensional deflection and bending moment parameters, Equations 5-2 are written as:

$$\sigma_{\phi} = \frac{pR}{h} \left( \overline{w} \pm \frac{3 \nu \overline{M}_{X}}{\sqrt{3 (1-\nu^{2})}} \right), \quad \sigma_{X} = \pm \frac{pR}{h} \frac{3\overline{M}_{X}}{\sqrt{3 (1-\nu^{2})}}$$
 (5-3)

Hence, for the stated problem we find:

(1) Stresses at maximum deflection (hoop stress) location

$$\sigma_{\phi} = \frac{pR}{h} = \left(\overline{w}_{max} + \frac{3 \nu \overline{M}_{xcor.}}{\sqrt{3(1-\nu^2)}}\right) = 252 p$$

$$\sigma_{x} = \pm \frac{3pR}{h} \sqrt{\frac{\overline{M}_{xcor}}{3(1-\nu^{2})}} = \pm 61.1 p$$

(2) Stresses at maximum bending moment location

$$\sigma_{\phi} = \frac{pR}{h} \left( \overline{w}_{cor.} + \frac{3 \nu \overline{M}_{xmax}}{\sqrt{3(1-\nu^2)}} \right) = 16.2 p$$

$$\sigma_{x} = \pm \frac{3pR}{h} \frac{\overline{M}_{xmax}}{\sqrt{3(1-\nu^{2})}} = \pm 73.9 p$$

The magnitude of the transient pressure, p, can be approximated by use of expressions given in Reference 2-1 or, when practical, determined experimentally. If we assume the change in pressure resulting from a valve closure situation to be p = 110 psi, then the above stresses are respectively:

(1) 
$$\sigma_{x} = 27,600 \text{ psi}$$
  
 $\sigma_{x} = \pm 6,710 \text{ psi}$ 

(2) 
$$\sigma_{\phi} = 1,780 \text{ psi}$$

$$\sigma_{x} = 8,110 \text{ psi}$$

Note that these stresses are caused by pressure transients and must be added to operating pressure stresses. Thus, for an operating pressure,  $p_0$ , of 150 psi, the largest hoop stress predicted would be:

$$\sigma_{\phi} = \frac{p_0^R}{h} + 27,600 = 42,600 \text{ psi}$$

#### VI. ADVANCED PROBLEMS

# A. EFFECT OF AXIAL PRE-STRESS

The present analysis assumes that the liquid propellant duct subjected to pressure transients is free from axial forces or any other pre-stress conditions. A recent investigation (Ref. 3-3) considers the effect of axial pre-stress for the case of axi-symmetric response of an infinite cylindrical shell subjected to a moving pressure wave. This analysis clearly shows that such pre-stress conditions can have a pronounced quantitative and qualitative effect upon shell response. In particular, it is shown that axial pre-tension increases the critical speed, while axial pre-compression will decrease the critical speed. The primary sources of pre-stress in a liquid propellant duct are

- (a) Thermal Effects
- (b) Assembly Stresses
- (c) Axial and/or transverse acceleration (body forces)

It should be noted that pre-stress conditions are not necessarily axi-symmetric, and when the pre-stress condition is of the non-axisymmetric type (pure bending, for example), shell response will be non-axisymmetric even though the pressure transients are axi-symmetric. Thus the extension of the present investigation to account for general pre-stress conditions will require the solution of the general thin-shell equations not restricted to axial symmetry.

#### B. EFFECT OF SHEAR DEFORMATION AND ROTATORY INERTIA

The present investigation neglects the effects of shear deformation and rotatory inertia. A preliminary assessment of this effect is contained in Reference 3-1, where it is shown that significant deviations from simple shell theory are possible depending upon the speed of propagation of the pressure pulse, duct thickness, and other physical parameters of the problem. The results of Reference 3-1 may be extended to obtain some refined design data of the type generated in the present investigation. We note that although

these effects may change the presently submitted design data for some combination of the problem parameters, the influence of shear deformation and rotatory inertia could be of paramount importance when liquid propellant ducts are made of moderately thick material or utilize sandwich construction.

#### C. LARGE ELASTIC DEFORMATIONS

The equations of motion which characterize duct behavior in the present investigation assume that sufficiently small deformations will occur, i.e., radial deformation of the duct median surface is assumed to be small compared to duct thickness ( w << h) Although this results in somewhat conservative design data, the extent to which this condition may be violated and the resulting penalty paid in terms of additional weight is not known. The presently used shell theory is linear and methods for solution utilize the principle of superposition. A shell theory which permits moderately large deflections will result in non-linear, partial differential equations of motion. The solution of such a system of equations is very difficult, and an initial research study will reveal to what extent useful design data can be generated.

#### D. VARIATION OF BOUNDARY CONDITIONS

Only two sets of boundary conditions have been studied in this report: simple-simple and clamped-clamped. The approach used in this investigation admits the satisfaction of the following set of boundary conditions:

At 
$$x = 0$$
, and  $x = 1$ , one member of each of

the products ( Qw ) and (  $M_X^{w^i}$ ) vanishes.

Since we may specify four different homogeneous boundary conditions at each end of the duct, there are ten physically distinct combinations of (admissible) homogeneous boundary conditions which may be imposed on the duct. Thus it may be concluded that there exist eight additional cases which remain to be solved by the method of this investigation. Their utility for design information rests upon detailed hardware considerations.

# E. DUCTS OF VARYING THICKNESS

The present analysis may be modified to encompass dynamic response calculations of ducts with variable thickness. In general, this will result in mode shapes characterized

by non-elementary functions or defined in numerical form. Although the present technique of separation of variables will remain unaltered in principle, the analysis will require substantial alteration and make extensive use of approximate and numerical methods.

### F. INTERACTION OF FLUID AND DUCT

In the present analysis it is assumed that no interaction takes place between the fluid and the duct, i.e., the fluid pressure forces are assumed to be known and are applied to the duct. However, when the duct deforms it applies forces to the fluid, and, conversely, the compressed fluid exerts forces upon the duct. It is obvious that this interaction affects the over-all motion of the fluid-duct system. To study this phenomenon, it will be necessary to modify the present shell model. The equations of motion of a compressible fluid must be written in cylindrical coordinates, and the motion of shell and fluid is coupled by appropriate interface conditions. An analytical assessment of this phenomenon is possible, but its effects upon the presently generated design data is not known. An initial research type study of this phenomenon is suggested to develop the apparatus necessary to obtain improved design data.

#### VII. CONCLUSIONS AND RECOMMENDATIONS

# This study clearly shows that:

- (a) Structural dynamic effects due to pressure transients are significant and often give rise to high stresses which may cause failure in liquid propellant ducts.
- (b) These effects may be assessed both qualitatively and quantitatively by methods of calculation which are detailed in the present report.

Methods which have been developed to date are adequate and may be extended. It is felt that further work in this area will add to design efficiency (maximum strength to weight ratio) and improve the reliability of propulsion systems. It is recommended that further work be conducted in the areas discussed below:

- (a) The present method of calculation depends on series summation of modal solutions. The computer time required to obtain accurate solutions is often excessive. A novel and efficient method to circumvent this problem has recently become available. It is suggested that this technique be investigated and adapted to the pressure transient problem.
- (b) Preliminary calculations using a shell theory which includes the effect of shear deformation and rotatory inertia indicate that in some circumstances these effects may be important. It is, therefore, suggested that the regions of importance be delineated and a set of refined design charts be constructed which incorporate these effects.
- (c) The present analysis accounts only for two types of boundary conditions, clamped-clamped and free-free. Since a variety of other cases appear in practice, it is suggested the design charts be extended to cover a multitude of combinations of boundary conditions on the duct.
- (d) The present analysis neglects the interaction between fluid and duct. Since this effect, in some circumstances may be important, it is suggested that an analytical study be undertaken to assess its influence upon design stresses.
- (e) The present analysis is concerned only with homogeneous ducting. It's known that considerable weight saving can be affected by using sandwich construction particularly when large and massive ducts are required. The present analysis techniques may be readily extended to investigate the response of cylindrical sandwich ducts to fluid pressure transients.

- (f) Almost all work to date in this area has been of an analytical nature. It is felt that an experimental program with particular emphasis on the measurement of the time history of fluid pressure transients and dynamic response of the duct and their relationship is highly desirable. This should also include correlation with the analytical results obtained in the present study.
- (g) The effect of damping on the dynamic response of cylinders to traveling pressure transients was found to be in general very significant. However, there are no methods available that can be used to predict accurate damping coefficients. Consequently, it is recommended that a study be performed specifically in the area of damping.

# APPENDIX A RESULTS OF LITERATURE SURVEY

The literature survey conducted revealed the existence of at least ten publications of direct applicability to the present investigation. References 1 through 11 are restricted to cylindircal shells subjected to axi-symmetric, moving load, moving in the direction of the shell axis, with constant speed. References 1 through 7 treat the shell of unbounded length, while references 8 through 11 are concerned with shells of finite length. A brief summary of the key aspects of each reference follows:

# THE SHELL OF UNBOUNDED LENGTH:

#### Reference 1:

This paper considers the deformation of an infinitely long thin-walled cylindrical tube due to a shock wave inside the tube. It is established that the deformation becomes considerable when the velocity of the shock wave is near a certain critical velocity of the tube. Other sections of this work treat the gas dynamic aspects of the shock front as it interacts with the structure. It is believed that the paper is in error for the case of supercritical speeds. The analysis considers only simple shell bending theory, a sharp pressure step, and solutions appears to be valid for subcritical speeds only.

#### Reference 2:

This short paper, which was originally published in the official journal of the Russian Academy of Sciences, deals with the stability and deformation of an infinitely long cylindrical shell. The shell is assumed to be under the influence of a ring line load, which moves in the direction of a shell generator at constant speed. The influence of load speed on deformation and the significance of critical speeds with respect to shell stability are evaluated. The author uses simple shell bending theory and it appears that his solutions are valid only for the subcritical speed range.

#### Reference 3:

An infinite cylindrical shell loaded by a step pressure wave is used to study the importance of bending in a dynamic system with a moving, discontinuous load. The case of an axially loaded thin steel shell submerged in water is discussed at length. A parameter study is run to determine the affect on shell behavior of changes in load speed, external damping and shell thickness. Simple shell bending and pure membrane theory are considered.

#### Reference 4:

This paper considers the response of a circular cylindrical shell subjected to a moving ring load with a constant velocity. A Fourier integral approach is used. Solutions are obtained within the frame work of Timoshenko-Love theory and Flügge shell theory. Both axial and transient inertia are considered, but it is shown that the longitudinal coupling effects are small. The solution obtained appears to be valid for the subcritical speed range only.

#### Reference 5:

This paper considers the axially symmetric dynamic response of an infinite circular cylindrical shell to a moving pressure load. The cylinder is subjected to a constant axial prestress. It is shown that axial prestress has a significant effect upon dynamic response. Solutions obtained in this paper are valid for both subcritical and supercritical speed regimes. The concept of group and phase velocity are utilized to determine the steady state response for supercritical load speeds.

#### Reference 6:

This paper considers the dynamic response (axially symmetric) of an infinite cylindrical tube subjected to a moving step pressure. A Timoshenko type shell theory is used, i.e., in addition to flexural response, the effects of shear deformation and rotatory inertia are considered. Shell response using this theory can differ radically when compared to the more elementary theories, particularly in the high speed regime.

#### Reference 7:

This investigation treats the dynamical response (axially symmetric) of an infinite cylindrical shell when subjected to a step pressure discontinuity moving in the axial direction of the shell. The shell is submerged in fluid and acoustic radiation is accounted for. The shell theory used is of the Timoshenko type, i.e., shear deformation and rotatory inertia are considered in addition to bending and membrane deformation. Because of the effective damping due to the acoustic medium, no critical speeds are shown to exist. Comparison with lower order theories are satisfactory.

#### THE SHELL OF FINITE LENGTH

#### Reference 8:

This work represents an analysis of rotationally symmetric motions of a thin cylinder caused by the passage of a pressure front of constant velocity along the axis of the cylinder. The method of virtual work is applied to a generator of the cylinder which is then treated as a beam on the elastic foundation. Using free-free end conditions, only simple shell bending theory is used.

#### Reference 9:

The differential equation for radial vibrations of a thin cylindrical shell is derived by Hamilton's principle for the case of constant internal and transient external pressures. Pressures are assumed symmetrical about the cylinder axis of symmetry and the natural frequencies and mode shapes are obtained. The forced motion problem is presented using integral transform methods. A specific solution is developed where the external pressure is a step function moving over the cylinder in the axial direction. Simple shell bending theory is used and only simple supports are considered.

#### Reference 10:

Using simple bending theory of cylindrical shells, the transient response of a finite cylindrical shell of circular cross-section subjected to a moving pressure discontinuity is obtained for the axially symmetric case. The shell is simply supported at both ends, and the method of Fourier series is employed. Dynamic amplification factors are determined for some parameter ranges of the problem.

#### Reference 11:

An exact, formal solution is presented for the dynamic response of a cylindrical shell of finite length under axi-symmetric, but otherwise arbitrarily distributed, time dependent surface-tractions, for arbitrary initial conditions and (admissible) homogeneous boundary conditions. The solution is obtained in terms of the eigenfunctions associated with the free vibration of the shell, and appropriate orthogonality and normalization conditions are formulated. The free vibration problem for a freely supported shell is solved, and two examples of shell response to transient loading conditions are presented. The theoretical development and its application are carried out within the framework of a theory which accounts for the effect of shear deformation and rotatory inertia. Comparisons with elementary shell theories which neglect these effects are presented.

# STABILITY OF A CYLINDRICAL SHELL UNDER THE INFLUENCE OF A MOVING PRESSURE LOAD\*

by B. L. Prisekin

(Novosibirsk)

The stability and deformation of an infinitely long cylindrical shell is examined. The shell is under the influence of a load which moves in the direction of a shell generator at constant speed. The influence of load speed on deformation and the significance of critical speeds with respect to shell stability are evaluated.

1. A line load of intensity P is uniformly distributed in the circumferential direction and concentrated in the direction of the shell axis. The load moves with speed  $v_0$  in the direction of the shell axis along an infinite cylindrical shell. Axisymmetric response will result, and the equations of motion are  $^{(1)}$ :

$$-D \frac{\partial^{4} w}{\partial x^{4}} - \frac{1}{R} \frac{\partial^{2} \Phi}{\partial x^{2}} = P \delta \left(-v_{o} t + x\right) + \rho h \frac{\partial^{2} w}{\partial t^{2}}$$

$$\frac{1}{Eh} \frac{\partial^{4} \Phi}{\partial x^{4}} = \frac{1}{R} \frac{\partial^{2} w}{\partial x^{2}}$$
1.1

where  $\delta$  (-v<sub>o</sub> t + x) ~ the Dirac delta function, D ~ bending stiffness, h ~ thickness, R ~ radius. Evidently the solution of equation (1.1) can be represented by:

$$w = w (\xi), \Phi = \Phi (\xi), \xi = -v_0 t + x$$

\*Izvestiya Akademii Nauk SSSR, Otdelenie Tekhnicheskikh Nauk (Mekhanika i Mashinostroenie), No. 5, 1961, pp. 133-134. We assume a solution of the system (1.1) in the form

$$\mathbf{w} = \frac{1}{2\pi} \int_{-\infty}^{\infty} \mathbf{A}(\boldsymbol{\omega}) \boldsymbol{e}^{-\mathbf{i}\boldsymbol{\omega}\boldsymbol{\xi}} d\boldsymbol{\omega} : \frac{\partial^{2}\Phi}{\partial \boldsymbol{\xi}^{2}} = \frac{1}{2\pi} \int_{-\infty}^{\infty} \mathbf{B}(\boldsymbol{\omega}) \boldsymbol{e}^{-\mathbf{i}\boldsymbol{\omega}\boldsymbol{\xi}} d\boldsymbol{\omega}$$
(1.2)

We find

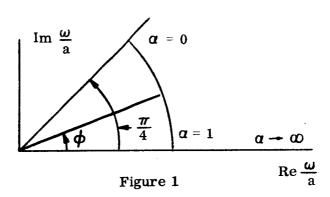

$$A(\omega) = -\frac{P}{\Delta}; B(\omega) = \frac{Eh}{R} A(\omega)$$

$$\Delta = D\omega^{4} - \rho h v_{o}^{2} \omega^{2} + \frac{Eh}{R}$$
(1.3)

Let us denote the root of the quation  $\Delta = 0$  by  $\omega_0$  where

$$\omega_0 = a e^{\frac{i\pi}{4}}$$
, where  $v_0 = 0$ ,  $a^4 = \frac{Eh}{DR^2}$ 

Then the poles of the integrand function in (1.2) will be  $\omega = \omega_0$ ,  $\frac{a^2}{\omega} = \frac{a^2}{\omega}$ . The roots  $\omega_0$  in the complex plane  $\frac{\omega}{a}$  lie on the circular segment when  $0 \le \alpha \le 1$ , where  $\alpha = \sqrt{3(1-\nu^2)} \frac{\rho R v_0^2}{Eh}$  and on the real axis when  $\alpha > 1$  (see Figure 1).

Evaluating integrals (1.2) with the help of residues, we obtain:

$$\mathbf{w} = \frac{-i \mathbf{P}}{2\mathbf{D} \left(\boldsymbol{\omega}_{0}^{2} - \frac{\mathbf{a}^{4}}{\boldsymbol{\omega}_{0}^{2}}\right)} \left[ \frac{1}{\boldsymbol{\omega}_{0}} e^{-i \boldsymbol{\xi} \boldsymbol{\omega}_{0}} + \frac{\boldsymbol{\omega}_{0}}{\mathbf{a}^{2}} e^{-\frac{i \boldsymbol{\xi} \mathbf{a}^{2}}{\boldsymbol{\omega}_{0}}} \right] : \boldsymbol{\xi} > 0$$

$$\mathbf{w} = \frac{-i \mathbf{P}}{2\mathbf{D} \left(\boldsymbol{\omega}_{0}^{2} - \frac{\mathbf{a}^{4}}{\boldsymbol{\omega}_{0}^{2}}\right)} \left[ \frac{1}{\boldsymbol{\omega}_{0}} e^{-i \boldsymbol{\xi} \boldsymbol{\omega}_{0}} + \frac{\boldsymbol{\omega}_{0}}{\mathbf{a}^{2}} e^{-\frac{i \boldsymbol{\xi} \mathbf{a}^{2}}{\boldsymbol{\omega}_{0}}} \right] : \boldsymbol{\xi} < 0$$

$$(1.4)$$

For the potential function we have, according to (1.2), (1.3)

$$\frac{\partial^2 \Phi}{\partial \xi^2} = \frac{Eh}{R} w$$

We note that the solution is symmetrical with respect to  $\xi=0$ . When  $\alpha>1$  a real solution does not exist. From the equality  $\alpha=1$  we obtain a formula for the critical speed

$$\omega_{\rm o} = \sqrt{\frac{\rm Eh}{3(1-\nu^2)}} \frac{1}{\rho R}$$

In what follows we shall examine only the case where  $0 \le \alpha \le 1$ , in other words  $v_0 < v$ . In this case we may characterize the root  $\omega_0$  in the form (Figure 1).

$$\omega_0 = a e^{i \phi}$$
; tan  $\phi = \sqrt{\frac{1-\alpha^2}{\alpha}}$ 

Then the relation (1.4) assumes the form ( $\xi > 0$ )

$$w = -\frac{P}{2a^3 D \sin 2\phi} e^{-\xi a \sin \phi} \cos (\xi a \cos \phi - \phi) \qquad (1.5)$$

In the case of a static load on the shell in (1.5) we take  $v_0 = 0$ . It follows from (1.5) that when  $v_0 \rightarrow v_1$  ( $\phi \rightarrow 0$ ) the magnitude of the bending moment grows as  $\frac{1}{\sin 2\phi}$ . This is explained as follows: The homogeneous system (1.1) has solutions in the form of traveling sinusoid waves

$$w = A e^{ik (x-vt)}$$
;  $\Phi = B e^{ik (x-vt)}$ 

and for the relation between wave number k and wave speed v we have

$$\rho \text{ hv}^2 = D \text{ k}^2 + \frac{Eh}{R^2 \text{ k}^2} \text{ , or } \frac{v^2}{v_0^2} = \frac{1}{2} \left( \frac{\text{k}^2}{\text{a}^2} + \frac{\text{a}^2}{\text{k}^2} \right)$$
 (1.6)

From (1.6) we see that the minimum speed of traveling waves is equal to  $v_0$ . This result explains the increase in deflection of the shell as  $v - v_*$ , and also explains why the system (1.1) has no solution for  $v_0 - v$ . For steel shells the value of  $v_0$  is in the area 200-670 m/sec, for corresponding  $\frac{h}{R}$  from  $\frac{1}{400}$  to  $\frac{1}{40}$ .

- 2. Let us evaluate the effect of speed of propagation of the load for the case of shell instability. We assume the shell deforms symmetrically with respect to  $\xi$  = 0. Let us compare the two conditions of the shell
  - (1) The load P° is stationary

$$\mathbf{w}^{\circ} = -\frac{\mathbf{P}^{\circ}}{2\mathbf{a}^{3}\mathbf{D}} \boldsymbol{\varrho} \sqrt{\frac{\boldsymbol{\xi}\mathbf{a}}{2}} \quad \cos \quad \left(\frac{\boldsymbol{\xi}\mathbf{a}}{2} - \frac{\boldsymbol{\pi}}{4}\right) \quad ; \quad \frac{\boldsymbol{\partial}^{2}\boldsymbol{\Phi}^{\circ}}{\boldsymbol{\partial}\boldsymbol{\xi}^{2}} = \frac{\mathbf{E}\mathbf{h}}{\mathbf{R}} \mathbf{w}^{\circ} \quad (2.1)$$

(2) The load moves with speed

$$w = \frac{P^*}{2a^3D} \qquad e^{-\xi a \sin \phi} \cos (\xi a \cos \phi - \phi); \qquad (2.2)$$

$$\frac{\partial^2 \Phi}{\partial \xi^2} = \frac{Eh}{R} \quad \text{w} \quad \text{where } P^* = \frac{P}{\sin 2 \phi}$$
 (2.3)

From the above formulae we see that the shape of the deformed zone near the point of application of the line load P and the character of the stress condition differ insignificantly if  $v_0 < 0 > v_*$  (It follows from Figure 1 that  $\frac{\pi}{4} \ge \phi \ge 0$  when  $0 \le v_0 \le v_*$ ). Figure 2 shows the variation of  $\phi$  as a function of  $v_0$ . Consequently, it follows that the magnitude of the load will differ insignificantly for both cases and we may take approximately

$$P^{\circ} * = P^*$$

when the value of the critical load P\* is sufficiently high. Comparing with (2.3) we obtain

$$P_* = P_*^{\circ} \sqrt{1-\alpha^2}$$
 (2.4)

The variation of  $\frac{P_*}{P_*}$  as a function of the load speed  $v_0$  is given in Figure 2. It shows that for a broad range of values of  $v_0$  there is little reduction of the critical load compared to its static value. Only for the speed range corresponding to  $0.7 < \alpha < 1$  there occurs a sharp reduction in the magnitude of P.

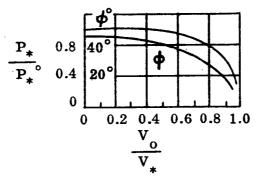

Figure 2.
