CONTENTS

ACKNOWLEDGEMENTS

The work at the Southwest Center for Advanced Studies was supported by NASA Research Grant NSG 269-62 and by National Science Foundation Grant, GP 926. One of us (B.C.F.) is also indebted to the North Texas State University, Denton, Texas, for the award of a research assistantship.

The computations necessary for the compilation of this work were performed using the facilities of the Computation Center at M.I.T., Cambridge, Massachusetts; at the Space Track Research and Development facility, Hanscom Field, Massachusetts; and at the Southern Methodist University, Dallas, Texas.

PART I

Vertical Cut-off Rigidities and Asymptotic Directions of Cosmic Ray Particles Arriving at Different Geographic Locations

1.1 INTRODUCTION

The cosmic ray particles which arrive at any point on the earth's surface have undergone deflection in the geomagnetic field. In order to relate the time variations observed on the ground to the time variations and departure from isotropy of the primary cosmic radiation in space, it is essential to make full allowance for these deflections in the analysis of the data. To this end, the asymptotic direction of approach $\vec{A}(N, \theta, \phi)$ of a cosmic ray of rigidity N, which arrives at the earth from the direction θ, ϕ has been defined as the direction from which the particle was moving prior to its entry into the geomagnetic field. (See Figure 1.)

Except for the special case of asymptotic direction lying in the equatorial plane of a simple dipole field, there are no analytic expressions for the asymptotic directions. Evaluation of the asymptotic directions has, therefore, been possible only through either model experiments, in which a small model of the earth and its field is used to experimentally simulate the actual physical situation, or through numerical integration of the equations of motion of cosmic ray particles. The former method has been exploited extensively by Malmfors (1945) and Brunberg and Dattner (1953), while the latter has been pursued by Stoermer (1955), Jory (1956), and Lust and Simpson (1957).

Without exception, all the above data have been obtained using a dipole simulation of the geomagnetic field. Experimental studies of the cosmic ray latitude effect have demonstrated the inadequacy of this simulation, and studies of the geomagnetic cut-off effect have illustrated that spherical harmonics up to the 6th degree have significant effects upon the cosmic radiation observed at the surface of the earth. While the introduction of such terms into the calculation of asymptotic directions results in a great increase in the number of arithmetic operations necessary to determine the orbit of a cosmic ray, the advent of high speed digital computers has made the problem tractable. The first such calculations were published by McCracken, Rao, and Shea (1962), and recently, Hatton and Carswell (1963), and others have added to the totality of such data. The majority of the available data pertains to cosmic rays arriving at the earth from the vertical, a serious deficiency in studies of the totality of cosmic radiation arriving at the earth's surface.

In the present work, the data previously obtained have been gathered together, and have been augmented by data for eight directions inclined to the vertical (for each value of the rigidity).

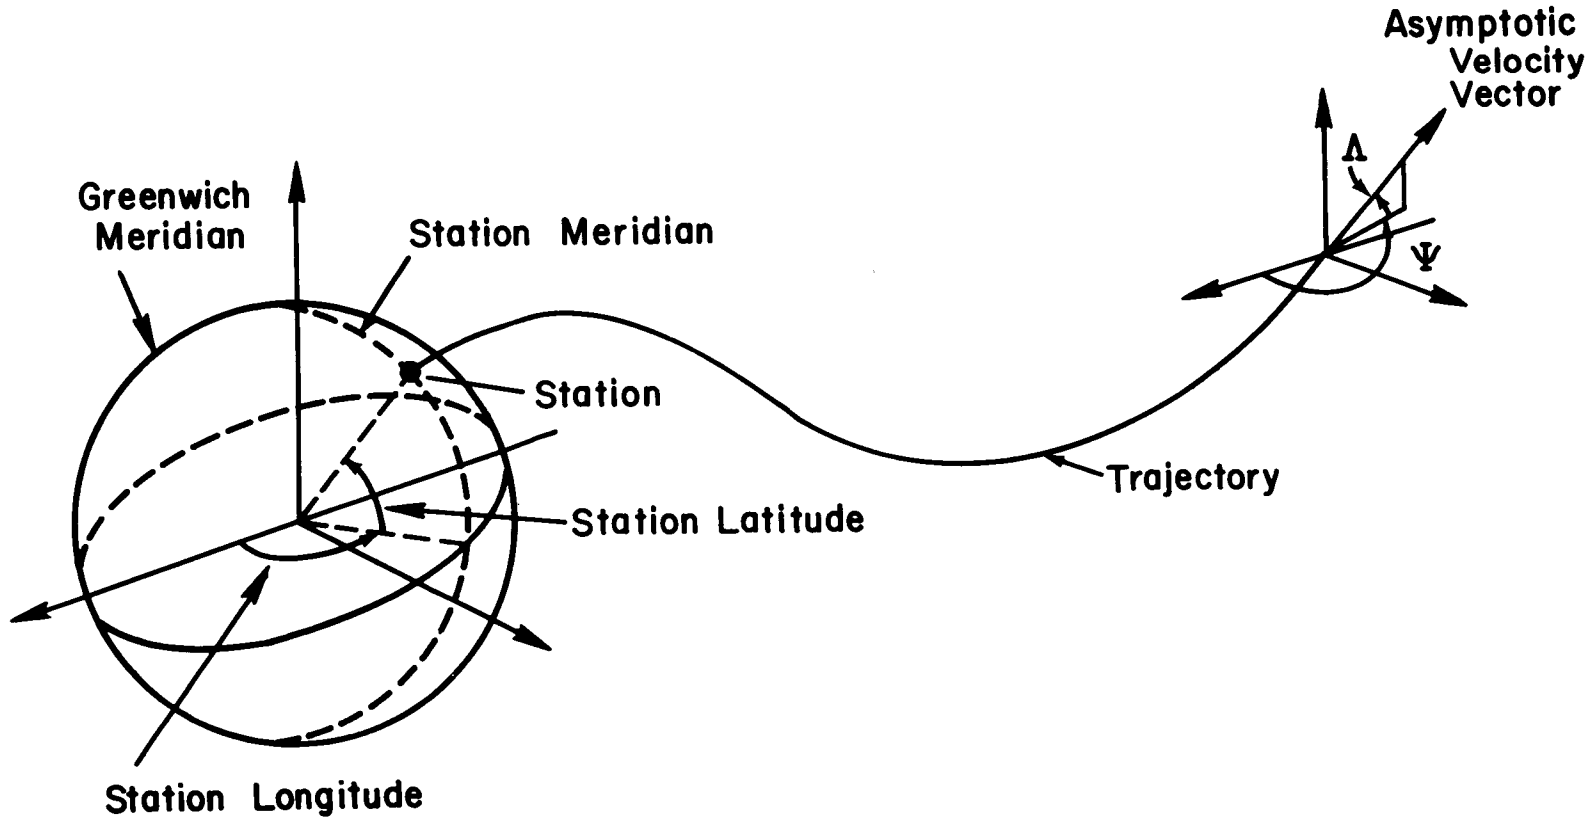

FIGURE 1

The trajectory of a charged particle through the geomagnetic field

Data are presented for 79 points on the earth's surface. Variational coefficients calculated using these asymptotic direction data are also presented.

1.2 THE BASIC MATHEMATICAL FORMULAE

We will first discuss in some detail the mathematical statement of the problem and its solution, and then tabulate the data obtained for 79 points on the earth's surface.

The problem will be solved in spherical polar co-ordinates. The symbols used are:

$\vec{R}$	position vector of a cosmic ray particle
r	radial distance from the center of the earth
θ	co-latitude
ϕ	longitude measured eastward from Greenwich meridian
$\vec{v}$	cosmic ray velocity vector
v	magnitude of particle velocity
v_r, v_θ, v_ϕ	velocity components in r, θ, ϕ directions
c	velocity of light
m	inertial mass of cosmic ray ($m = m_o \left(1 - \frac{v^2}{c^2}\right)^{-\frac{1}{2}}$ where m_o is rest mass)
$\vec{B}$	vector magnetic induction in gauss
e	cosmic ray charge in e.s.u.

The equation of motion of the particle in the Gaussian system of units is:

$$m \frac{d^2\vec{R}}{dt^2} = \frac{e}{c} \left(\frac{d\vec{R}}{dt} \times \vec{B} \right) \tag{1}$$

and this may be written in terms of the spherical co-ordinate system as follows:

$$\left.\begin{aligned} \frac{dv_r}{dt} &= \frac{e}{mc} \left(v_\theta B_\phi - v_\phi B_\theta \right) + \frac{v_\theta^2}{r} + \frac{v_\phi^2}{r} \\ \frac{dv_\theta}{dt} &= \frac{e}{mc} \left(v_\phi B_r - v_r B_\phi \right) - \frac{v_r v_\theta}{r} + \frac{v_\phi^2}{r\tan\theta} \\ \frac{dv_\phi}{dt} &= \frac{e}{mc} \left(v_r B_\theta - v_\theta B_r \right) - \frac{v_r v_\phi}{r} - \frac{v_\theta v_\phi}{r\tan\theta} \end{aligned}\right\} \tag{2a}$$

$$\left.\begin{aligned} \frac{dr}{dt} &= v_r \\ \frac{d\theta}{dt} &= \frac{v_\theta}{r} \\ \frac{d\phi}{dt} &= \frac{v_\phi}{r\sin\theta} \end{aligned}\right\} \qquad (2b)$$

This system of simultaneous linear differential equations can be integrated numerically if the components of the magnetic induction, B_r, B_θ, B_ϕ are known as explicit functions of r, θ, ϕ. If the field outside the earth is curl free, we may unambiguously define a magnetic potential U which can be expanded in spherical harmonics, thus

$$U(r,\theta,\phi) = a \sum_{n=0}^{\infty} \sum_{m=0}^{\infty} (g_n^m \cos m\phi + h_n^m \sin m\phi)\, P_n^m (\cos\theta) \left(\frac{a}{r}\right)^{n+1}$$

where g_n^m, h_n^m are the Gauss coefficients, $P_n^m (\cos\theta)$ are the partially normalized Legendre functions, and a is the average radius of the earth. [Chapman and Bartels (1951), Chapter 17] The magnetic induction at the point (r, θ, ϕ) is then given by

$$B_r = -\frac{\partial U(r,\theta,\phi)}{\partial r}, \quad B_\theta = -\frac{1}{r}\frac{\partial U(r,\theta,\phi)}{\partial \theta}, \quad B_\phi = -\frac{1}{r\sin\theta}\frac{\partial U(r,\theta,\phi)}{\partial \phi}$$

which, by using the equation for U, may be written as explicit formulae in r, θ and ϕ.

Hence, B is known at all points; and it is, therefore, possible to determine the trajectory of a cosmic ray particle by numerical integration of equation (2). In practice, the Gill modification of the Runge-Kutta integration process was employed (Gill, 1951). In this process, a knowledge of the position and velocity co-ordinates of one point on the trajectory is used in conjunction with the differential equations to give the co-ordinates of a subsequent point on the trajectory. Repeated application gives sufficient points to locate the trajectory in space.

In practice, we wish to know the direction in space from which a cosmic ray which ultimately arrives at some given point, from a specified direction, has initially come. Referring to equation 1 we note that if the sign of e and the direction of motion are reversed, the equation remains unaltered. That is, the trajectory of a negative particle leaving the earth is the same as that of a positive particle approaching the earth. To find the asymptotic direction of approach corresponding to a given location on the earth, P, a given cosmic ray momentum, and a given direction of arrival, we will determine the trajectory of a negative particle of the same rigidity leaving P

anti-parallel to the direction of arrival of interest. The trajectory is followed to a point far from the earth, at which point the direction of motion of the particle is calculated. This direction is the asymptotic direction of approach corresponding to the point P.

The problem, therefore, breaks down into three distinct stages:

1) the determination of the initial point on the trajectory,
2) determination of the trajectory to a point well-removed from the earth, and
3) calculation of the asymptotic directions.

These stages will now be considered individually. All calculations are made for a single nucleon. The results are immediately applicable to other particles since the trajectories of two particles of equal momentum to charge ratios (rigidities) are identical.

In the calculations, and in the statement of the initial conditions for any desired trajectory, we find it convenient to express all distances in terms of the average value for the radius of the earth.

1.2.1 The Initial Point on the Trajectory

We will consider calculating the asymptotic direction which corresponds to a point on the earth specified by geographic latitude λ , longitude η .

The initial distance from the center of the earth will be taken to be 20km above the surface of the earth. In the vicinity of this altitude, most cosmic rays undergo nuclear collisions. Taking the oblateness of the earth into account, the radial distance (in earth radii) to the initial point is

$$r_{initial} = \frac{1}{a} \left\{ b \left[1 - \epsilon^2 \cos^2 \lambda \right]^{-\frac{1}{2}} + 20.0 \right\}$$

where b = 6356.9 km is the minimum (polar) radius of the earth, ϵ is the eccentricity ($\epsilon^2 = 6.725 \times 10^{-3}$) of the earth, and a is the average radius of the earth.

$$\theta_{initial} = \frac{\pi}{2} - \lambda$$

$$\phi_{initial} = \eta$$

The velocity of the particle of momentum P Bev/c is given by

$$v = \frac{Pc}{\sqrt{R^2 + P^2}}$$

where R is the rest energy, 0.931 Bev. The three components of the velocity are

$$(v_r)_{\text{initial}} = v \cos Z$$
$$(v_\theta)_{\text{initial}} = -v \sin Z \cos A$$
$$(v_\phi)_{\text{initial}} = v \sin Z \sin A$$

where (Z,A) are the zenith and azimuth angles specifying the direction of arrival at the top of the atmosphere. A is measured eastward from geographic north.

1.2.2 Step by Step Determination of the Trajectory

As described previously, this is achieved using the Runge-Kutta integration process. The farther the negative particle recedes from the earth, the less important become the higher degree terms in the field expansion, and the radius of curvature of the trajectory becomes greater. Hence, as r increases, we may truncate the field expansion at lower degree terms, and increase the length of the step in the Runge-Kutta integration process. The following table indicates the highest degree terms which we have used at different distances from the center of the earth. The length of the Runge-Kutta step is changed when going from one of these ranges to the next.

Maximum Degree in Field Expansion	Range of Employment (Distance in Earth Radii)
6	$0 \leq r < 2.5$
5	$2.5 \leq r < 3.0$
4	$3.0 \leq r < 5.4$
3	$5.4 \leq r < 10.0$
2	$10.0 \leq r < 50.0$

After each step in the integration process, the value of r corresponding to the new point on the trajectory is examined. If it is less than 1.0, the trajectory has intersected the earth and integration ceases permanently. If it has entered a new range in the above table, the maximum degree employed in the field expansion and the Runge-Kutta step length are adjusted accordingly. At a number of pre-determined values of r, the magnitude of the velocity of the particle is computed from the current components of the velocity. A difference between this current value of v and the initial value is indicative of systematic errors in the integration procedure. The magnitude of these errors is very sensitive to the length of the step in the Runge-Kutta process, and reducing the step length will reduce the errors to an insignificant level. Integration is usually continued until $r \geq 25.0$. Once this value is attained, the calculation enters the third stage.

Knowing the position and velocity components at a far distant point on the trajectory, we wish to specify the direction of the particle velocity vector in terms of the geographic co-ordinate system.

The "asymptotic latitude" Λ is given by

$$\tan(\Lambda) = \frac{-v_\theta \sin\theta + v_r \cos\theta}{\sqrt{v_\phi^2 + (v_\theta \cos\theta + v_r \sin\theta)^2}}$$

and the "asymptotic longitude" ψ by

$$\psi = \phi + \arctan\left(\frac{v_\phi}{v_\theta \cos\theta + v_r \sin\theta}\right)$$

Knowing Λ and ψ, the problem is solved.

1.2.3 The Magnetic Field Specification

We have used the Finch and Leaton (1957) sixth degree expansion of the geomagnetic field in all asymptotic direction calculations reported herein. The Finch and Leaton coefficients employed are given in Table 1. The basic Fortran Programme has already been published elsewhere (McCracken, Rao and Shea, 1962).

1.3 VERTICAL CUT-OFF RIGIDITIES

The basic programme used for the computation of trajectories is potentially useful for many other types of investigations which consider the motion of charged particles in the geomagnetic field. For example, in our laboratory we have introduced modifications in order to calculate:

a) Cut-off rigidities

b) The trajectories of particles in the Van Allen Radiation belts

c) The detailed trajectories of particles in the geomagnetic field

d) Asymptotic directions, the effect of a ring current being added to the geomagnetic field.

e) Asymptotic directions, the effect of magnetosphere being added to the geomagnetic field.

f) Particle trajectories in the presence of both electric and magnetic fields.

Reference to the original report (McCracken et al, 1962) should be made if the reader wishes

to employ some such variant of the basic programme himself.

A knowledge of the threshold rigidities for cosmic ray particles arriving at different geographic locations on the globe is of great importance in the study of the spectrum and time modulations of primary cosmic ray intensity. Freon and McCracken (1962) and Shea, Smart and McCracken (1965) have demonstrated the importance of using a high degree simulation of the geomagnetic field to calculate the vertical cut-off rigidities accurately. We have derived the vertical cut-off rigidities for all the 79 stations for which we have tabulated the trajectories. To allow for the effects of the penumbra, the cut-off rigidities have been obtained by detailed computation of trajectories for rigidities separated by 0.01 bv intervals. The details of these calculations are published separately. (Shea, Smart and McCracken, 1965)

In Table 2 is presented the list of 79 stations, their geographic co-ordinates, and the vertical cut-off rigidities, obtained using the Finch and Leaton simulation of the geomagnetic field. For some of these stations the vertical cut-off rigidities obtained using the Jenson and Cain (1964) simulation of the geomagnetic field are also listed. The geographic co-ordinates used are those normally recommended by the stations themselves and agree with those listed by the Times Atlas to within 0.2° (45 km longitudinal distance at equator). All longitudes are measured to the east of the Greenwich meridian.

The asymptotic directions of approach of cosmic ray particles of different rigidities arriving at different stations are tabulated in the following pages. For each station, the asymptotic directions of approach for particles arriving with zenith angles of 0° (vertical), 16° and 32° in the north-south and east-west geomagnetic azimuths are tabulated.

TABLE 1

Table of Finch and Leaton coefficients as used in the asymptotic direction calculations. The input data for the computing programme, C and D, are obtained from the gauss coefficients g_n^m, h_n^m by the multiplication by the given factor.

NOTE: For certain latitude stations all trajectories below the values given in the table fail to reach a solution; therefore, these cut-off values are listed as "less than."

PART II

Cosmic Ray Variational Coefficients for Different Stations

2.1 ASYMPTOTIC CONE OF ACCEPTANCE

In any study of the time variations of the cosmic radiation, a detailed knowledge of the dependence of the counting rate on the asymptotic direction is essential. In all such studies it is very useful to use the concept of the 'asymptotic cone of acceptance of a detector' which may be defined as the solid angle containing the asymptotic directions of approach which make a significant contribution to the counting rate of the detector. Detailed theoretical discussions have already been published by Rao, McCracken and Venkatesan (1962). We will, henceforth, refer to the aforementioned paper as Paper I. In this report we attempt to give only a brief account of the problem. However, before we adopt a rigid mathematical formulation, we will consider the problem qualitatively. In Figure 2 the asymptotic directions of approach of particles of selected rigidities between 2 and 100 bv and directions of approach into the atmosphere with zenith angles of 0^{o}, 16^{o}, and 32^{o} in the north-south and east-west geomagnetic planes are plotted on the geographical scale of coordinates. The four detector locations considered are sufficient to illustrate some of the important consequences of the use of the asymptotic cones of acceptance. The figure has been prepared on the basis of the asymptotic direction data tabulated in Part I. From a close examination of Figure 2, we can reach the following conclusions:

1.) The cones of acceptance in Figures 2A and 2B are wide in longitude, whereas the cones of acceptance of high latitude stations in Figures 2C and 2D are narrow. An anisotropy of small angular extent will, therefore, lie within the cones of acceptance shown in Figures 2A and 2B for many hours and for less than 2 hours in cones of Figures 2C and 2D. Furthermore, since at any time in A and B, only a relatively small fraction of the radiation will have come from the directions of abnormal intensity, the deviation in counting rate will be much smaller compared to those in C and D.

2.) The cone of acceptance in Figure 2D is about 50^{o} to the east of its meridian, whereas the cone of acceptance in Figure 2C is almost coincident with its meridional plane. Any anisotropy, therefore, will be seen by the station corresponding to 2D about three hours earlier than the station corresponding to 2C, even though both the stations are at the same geomagnetic latitude of about 70^{o}. At higher latitudes the time differences would be even greater, and they would still be appreciable at lower latitudes.

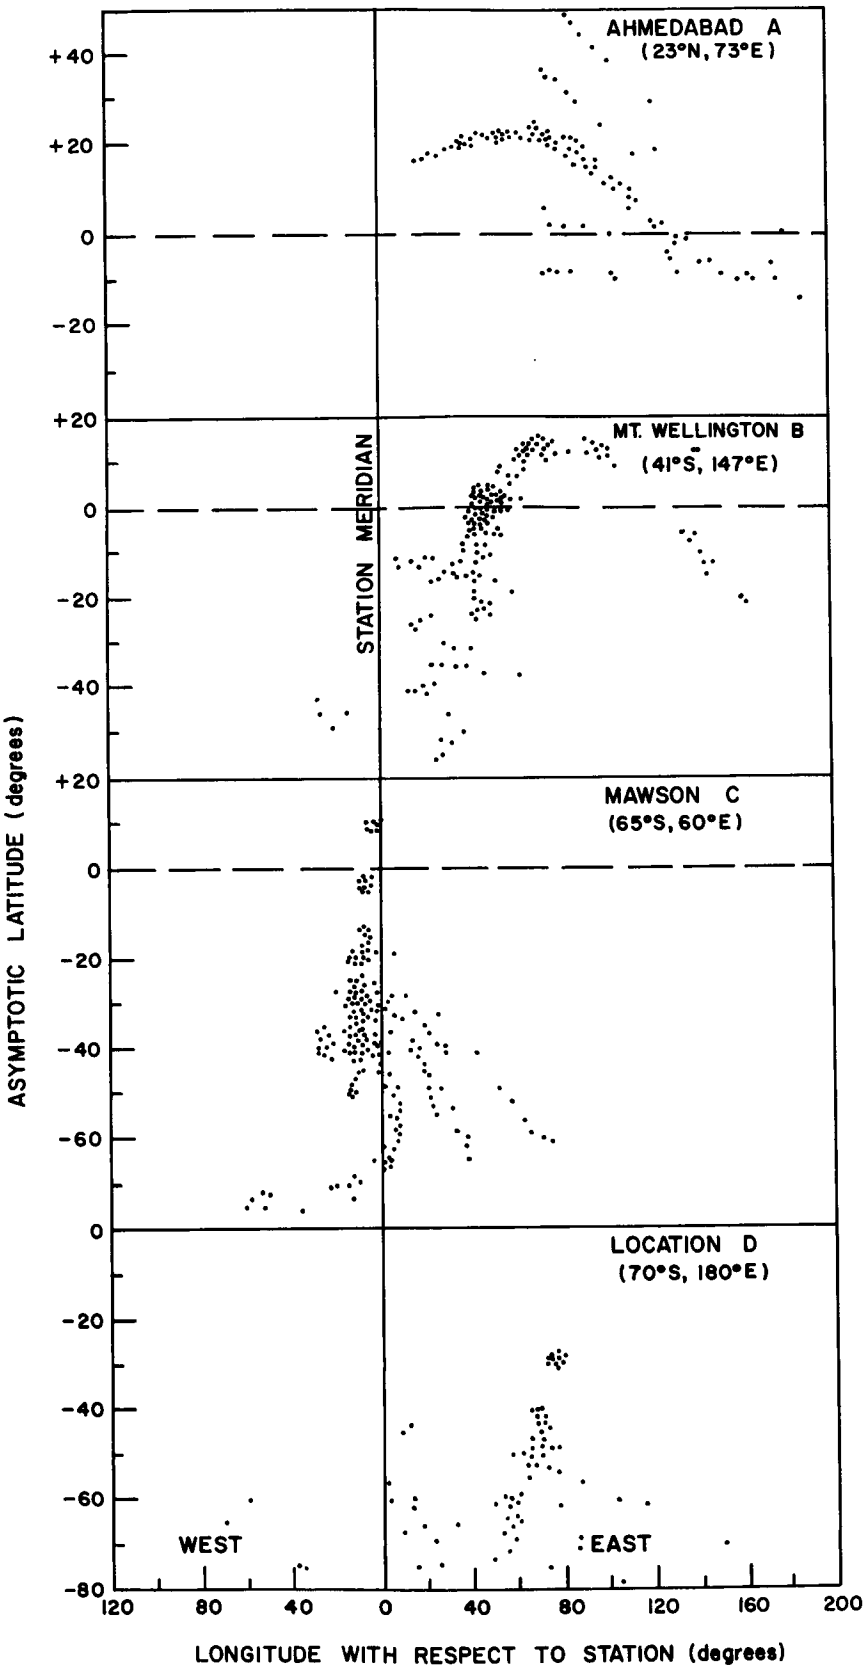

FIGURE 2

The Asymptotic Directions of Approach for Particles arriving at four locations. Location D has the same geomagnetic latitude as Mawson.

3. Even though the detector corresponding to Figure 2B is situated at a moderately high latitude (geographic 42^{o}, geomagnetic 52^{o}), it scans directions close to the equatorial plane, as does the detector corresponding to Figure 2A. Only the asymptotic cones of acceptance of very high latitude stations (as Figures 2C and 2D) make an appreciable angle with the equatorial plane. Consequently, a dependence of cosmic ray intensity on declination will become apparent as differences in time variations observed at stations at latitudes greater than about 50^{o}.

We may, therefore, anticipate that the geomagnetic field has the effect of causing the phase, duration and amplitude of a time variation that is due to any anisotropy in the cosmic radiation to vary from station to station and, to a lesser extent, from detector to detector at any one station. The variational coefficients provide a quantitative technique for calculating the variations which will be observed as the consequence of any assumed anisotropy.

2.2 COSMIC RAY VARIATIONAL COEFFICIENTS

2.2.1 The Concept of Variational Coefficients

To any desired degree of perfection, an arbitrary anisotropic flux of cosmic radiation can be approximated by dividing the whole 4π of asymptotic directions into a large number of small solid angles $\delta\Omega_i$, the differential cosmic ray intensity from all directions within the ith solid angle Ω_i, being $J_i(R)$, where R is the particle rigidity. For any arbitrary anisotropic flux of cosmic radiation, the counting rate of any detector at any time can then be calculated if we know how to calculate the counting rate due to the flux $J_i(R)$ from within each of the small solid angles Ω_i.

Let θ and ϕ be the zenith and azimuth angles specifying the directions of arrival of a cosmic ray at the top of the atmosphere. Let us consider an infinitesimally small solid angle $d\omega(\theta_o,\phi_o)$ in the direction θ_o, ϕ_o and rigidities within the interval R to R + dR. From Liouville's theorem, the flux of particles arriving from $d\omega$ that have originally come from asymptotic directions within Ω_i is $J_i(R)$ if, for rigidity R, $d\omega$ is accessible from Ω_i, and zero if inaccessible. The corresponding counting rate $dC(\Omega_i, R, \theta, \phi)$ at ground level when $d\omega$ is accessible is given by

$$dC(\Omega_i, R, \theta, \phi) = J_i(R)\cdot T(R,\theta,\phi)\, d\omega\, dR = J_i(R)S(R)Z(\theta,\phi)\, d\omega\cdot dR$$

where $T(R, \theta, \phi)$, a characteristic of the atmosphere, is assumed to be a separable function of direction and rigidity, namely, the product of $S(R)$ and $Z(\theta, \phi)$. Integrating over all directions of entry into the atmosphere, the counting rate due to radiation arriving from asymptotic directions within Ω_i is given by

$$\Delta C(\Omega_i,R) = J_i(R)S(R)Y(\Omega_i,R)\, dR \qquad (1)$$

where $Y(\Omega_i, R)$ is the integral of $Z(\theta,\phi)$ over all directions of θ, ϕ that are accessible to the detector from Ω_i for rigidity R. Now considering the special case of isotropic cosmic radiation, that is, the intensity from all asymptotic directions is $J_o(R)$, and putting $\Omega_i = 4\pi$, equation 1 reduces to

$$\Delta C(4\pi,R) = J_o(R)S(R)Y(4\pi,R)\, dR \qquad (2)$$

where $\Delta C(4\pi, R)$ is the total counting rate due to rigidities between R and R + dR. Dorman (1957) has defined the coupling constant $W(R)$ of a detector as

$$W(R) = (dc/dR) \cdot 1/N \qquad (3)$$

where dc is the counting rate due to the radiation in the rigidity range R to R + dR, and N is the total counting rate corresponding to the cosmic ray spectrum, $J_o(R)$. From the above definitions, it can be seen that $\Delta C(4\pi, R)$ in (2) is identical to dc in (3), and hence, equating these two quantities we obtain

$$S(R) = \frac{N \cdot W(R)}{J_o(R)Y(4\pi,R)}$$

and substituting in (1), we get

$$\Delta C(\Omega_i,R) = N \cdot W(R) \frac{J_i(R)}{J_o(R)} \frac{Y(\Omega_i,R)}{Y(4\pi,R)} \cdot dR \qquad (4)$$

In practice, we will take $J_o(R)$ to be the 'average' cosmic ray spectrum, N and $W(R)$ being the instrumental counting rate and coupling constant corresponding to this spectrum. We write $J_i(R) = J_o(R) + \Delta J_i(R)$, where $\Delta J_i(R)$ differs from one Ω_i to the next. Equation 4,

after integration over R, becomes

$$C(\Omega_i) = N \int W(R) \left[1 + \frac{\Delta J_i(R)}{J_o(R)} \right] \cdot \frac{Y(\Omega_i, R)}{Y(4\pi, R)} \cdot dR$$

Hence

$$\frac{dN(\Omega_i)}{N} = \frac{C(\Omega_i) - C_o(\Omega_i)}{N}$$

$$= \int W(R) \frac{\Delta J_i(R)}{J_o(R)} \frac{Y(\Omega_i, R)}{Y(4\pi, R)} \cdot dR \qquad (5)$$

where $C(\Omega_i)$ and $C_o(\Omega_i)$ are the counting rates due to particle fluxes $J_i(R)$ and $J_o(R)$ arriving from within the solid angle Ω_i. The quantity $dN(\Omega_i)/N$ is the fractional change in total counting rate produced by the cosmic ray intensity from Ω_i deviating from $J_o(R)$ by an amount $\Delta J_i(R)$, and as such is the basic quantity required in any study of a cosmic ray anisotropy.

We will assume that $\Delta J_i(R)/J_o(R)$ is a power law in rigidity, written as AR^{β}, where A is a function of asymptotic direction, and R is the rigidity in bv. Equation (5) reduces to

$$\frac{dN(\Omega_i)}{N} = A \cdot v(\Omega_i, \beta) \qquad (6)$$

where

$$v(\Omega_i, \beta) = \int W(R) \cdot R^{+\beta} \frac{Y(\Omega_i, R)}{Y(4\pi, R)} \cdot dR \qquad (7)$$

$v(\Omega_i, \beta)$ is called the variational coefficient of the detector corresponding to the solid angle Ω_i and spectral exponent β.

2.2.2 Properties of Variational Coefficients

If the cosmic ray intensity from within the solid angle Ω_i should be $J_o(1+A_i R^{+\beta})$,

and that from all other directions J_o, then the counting rate of an instrument will differ by an amount ΔN from the counting rate N that would be observed if the radiation intensity were J_o from all directions, where

$$\frac{\Delta N}{N} = v(\Omega_i, \beta) \cdot A_i$$

If in any particular problem J_o is the reference cosmic ray intensity, then $J_o A_i R^{+\beta}$ specifies the anisotropic component of the radiation that arrives from directions within solid angle Ω_i. The above equation expresses the fact that this anisotropic flux of radiation causes the counting rate of an instrument to deviate from the value which would be observed if the intensity were isotropic (and of magnitude J_o). If we know the variational coefficients for all possible solid angles Ω_i, the counting rate deviation corresponding to any assumed anisotropy can be calculated.

2.2.3 Evaluation of the Variational Coefficients

In the derivation of the data contained herein, the elementary solid angle Ω_i is defined by planes of constant geographic longitude at 0^o, 5^o, 10^o, ..., and by surfaces of constant geographic latitude spaced every 5^o on either side of the equator. To evaluate (7) for a given Ω_i we must evaluate $Y(\Omega_i, R)/Y(4\pi, R)$ as a function of R. This necessitates the determination of that fraction of the hemisphere above the detector that is accessible from asymptotic directions included within Ω_i. This can be determined if the asymptotic directions corresponding to all directions (θ, ϕ) and all rigidities are known.

In the evaluation of the variational coefficients, we have used the asymptotic directions corresponding to the cosmic ray particles of various rigidities arriving from nine directions: vertical, and from the geomagnetic north, south, east, west at zenith angles of 16^o, and 32^o. The approximation has been made, then, that, if a direction (θ_o, ϕ_o) is accessible from some elementary solid angle Ω_i for the kth rigidity R_k, then for $\theta_o \neq 0$, all directions within the solid angle defined by $\theta_o \pm 8^o$, $\phi_o \pm 45^o$ are accessible from Ω_i for rigidities in the range $(R_{k-1} + R_k)/2$ to $(R_k + R_{k+1})/2$. For $\theta_o = 0$, the approximation applies to the entire solid angle for which $\theta_o < 8^o$. In Paper I, it was shown that the integrals of $Z(\theta, \phi)$ over the above nine solid angles are approximately equal for a sea level neutron

monitor and the integral over $40^{o} < \theta < 90^{o}$ is negligible. An acceptable estimate of $Y(\Omega_i, r)$, therefore, is the number of above nine directions (θ_o, ϕ_o) that are accessible from infinity (from any asymptotic direction whatsoever).

From (7), the expression for $v(\Omega_i, \beta)$ can be written as

$$v(\Omega_i \beta) = \sum_{K=1}^{K} W(R_k) R_k^{+\beta} \cdot \frac{Y(\Omega_i, R_k)}{Y(4\pi, R_k)} \cdot \frac{(R_{k+1} - R_{k-1})}{2} \tag{8}$$

where summation extends from near the cut-off rigidity to 500 bv.

If we consider a simple form of anisotropy of the type

$$\Delta J_i(R) = AR^{+\beta} = f(\psi) \; R^{\beta} \cos \Lambda \tag{9}$$

where A is the amplitude of the anisotropy which is a separable function of the asymptotic latitude Λ and longitude ψ and which varies as cosine of declination. We can rewrite (6) as

$$\frac{dN(\Omega_i)}{N} = f(\psi) \, v(\Omega_i, \beta) \cos \Lambda \tag{10}$$

summing over all Ω_i,

$$\frac{dN(\psi_j)}{N} = f(\psi_j) \sum v(\Omega_i, \beta) \cos \Lambda = f(\psi_j) \, V(\psi_j, \beta) \tag{10}$$

where $dN(\psi_j)$ is the solid angle defined by the two meridional planes 2.5^{o} on either side of the meridional plane at geographic longitude ψ_j . $V(\psi_j, \beta)$ which are defined as the variational coefficients have been evaluated for the 79 stations for 10 values of β for $+0.6 \geq \beta \geq -1.5$. It may be pointed out that the variational coefficients for $\beta = 0.0$ represent the manner in which the cosmic ray particles from different asymptotic longitudes contribute

to the total counting rate of a detector.

2.3 APPLICATION TO THE DIURNAL VARIATION

From a knowledge of the variational coefficients, we can predict the amplitude and phase of the anisotropy observed at various stations. This is particularly useful in the study of the daily variation of cosmic ray intensity, provided the anisotropy considered is time invariant for at least 24 hours.

Consider an anisotropy that is an arbitrary function of η and is expanded as a Fourier Series

$$f(\eta) = J_o(R) \sum_{m=1}^{\infty} \alpha_m \cos_m (\eta - C_m)$$

where α_m and C_m are arbitrary amplitude and phase constants, and C_m the direction of viewing from which a maximum of the mth harmonic is seen. Referring to Figure 3, we may write

$$\eta = \psi + 15T - 180^o$$

and intensity from asymptotic longitude ψ as

$$f(\psi) = J_o(R) \left[\sum_{m=1}^{\infty} \alpha_m \cos m (\psi + 15T - 180^o - C_m) \right] \qquad (11)$$

where asymptotic longitude $\psi = (5i + 2.5)^o$, the mean longitude of all the particles arriving from the solid angles lying between $\psi = 5i^o$ and $\psi = 5(i + 1)^o$.

Inserting this value of $f(\psi)$ in (10) and summing over i, N(T) the deviation of the counting rate of detector at time T from the mean value N is

$$\frac{\Delta N(T)}{N} = \sum_{i=0}^{71} V(\psi_j, \beta) \cdot \sum_{m=1}^{\infty} \alpha_m \cos m (5i + 15T + 2.5 - 180 - C_m)$$

$$= \sum_{m=1}^{\infty} \alpha_m B_m \cos \left[m(15T - C_m - 180) + \gamma_m \right]$$

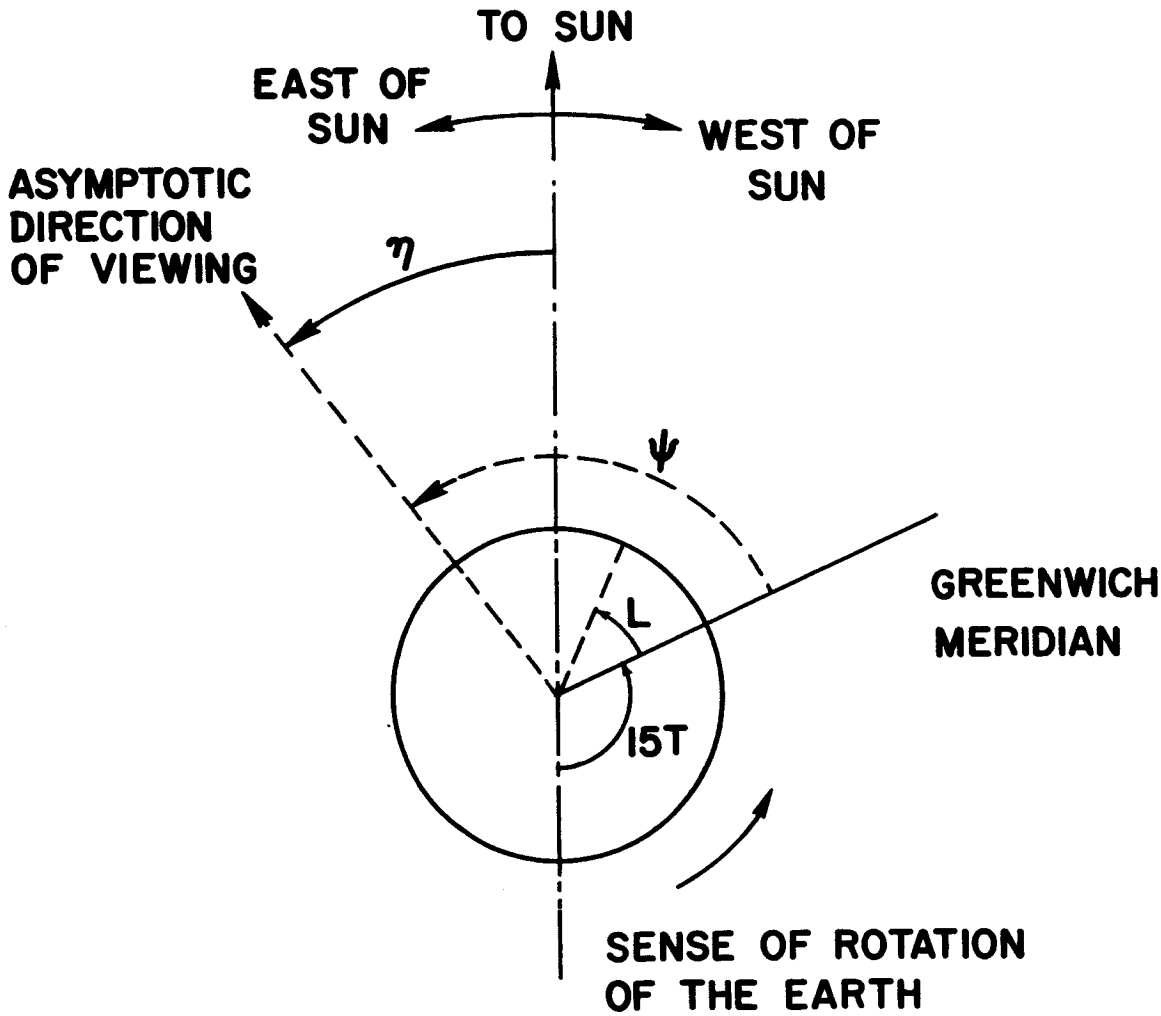

FIGURE 3

DEFINING THE ANGLES EMPLOYED TO SPECIFY THE ASYMPTOTIC DIRECTION OF VIEWING OF AN ARBITRARY STATION.

where

$$B_m^2 = \left\{ \sum_{i=0}^{71} V(\psi_j, \beta) \sin m \left[5i + 2.5 \right] \right\}^2$$

$$+ \left\{ \sum_{i=0}^{71} V(\psi_j, \beta) \cos m \left[5i + 2.5 \right] \right\}^2$$

and

$$\tan \gamma_m = \frac{\sum_{i=0}^{71} V(\psi_j, \beta) \sin m \left[5i + 2.5 \right]}{\sum_{i=0}^{71} V(\psi_j, \beta) \cos m \left[5i + 2.5 \right]}$$

where $\alpha_m B_n$ and $(-mC_m + \gamma_m)$ represent the amplitude and phase constants of the mth harmonic. The universal time at which the maximum intensity is observed is given by

$$T_m = \frac{180m + mC_m - \gamma_m}{15m} \quad \text{hours}$$

and the local time of maximum intensity, at a station whose geographic longitude is L, is given by

$$t_m = \frac{180m + mC_m - (\gamma_m - mL)}{15m} \text{ hours}$$

where the term $\frac{\gamma_m - mL}{15m}$ makes allowance for the deflection suffered by the cosmic rays in their passage through the geomagnetic field. This quantity is sometimes called the "geomagnetic bending" of the cosmic ray flux.

In the following pages, the variational coefficients for 79 stations and for 10 values of β, from $\beta = +0.6$ to $\beta = -1.5$, are tabulated. The relative amplitudes ($\alpha_m B_m$) and the corrections for geomagnetic bending ($\frac{\gamma_m - mL}{15m}$) for the 1st and 2nd harmonics for different values of β are also tabulated for each station. For 17 of these stations, the variational coefficients, the relative amplitudes and the correction for geomagnetic bending were published earlier (McCracken, Rao, and Shea, 1962). Due to 1) the adoption of the new cut-off rigidities calculated using Finch and Leaton simulation of the geomagnetic field (Table 2), 2) the more extensive rigidity ranges for which data

on the trajectories are now available, and 3) the availability of accurate asymptotic direction data for nine directions, the plot of the variational coefficients tabulated here may slightly differ in its fine structure compared to that published earlier. For the majority of the cases considered, the calculated correction for geomagnetic bending does not differ by more than 2^{o} for $\beta = 0.0$ and the calculated relative amplitudes by 5% for $\beta = 0$ when compared to the previously tabulated data.

TABLE 3

COSMIC RAY ASYMPTOTIC DIRECTIONS

In the following pages the asymptotic directions of approach of cosmic ray particles of various rigidities arriving at 79 different stations are tabulated. For each station the asymptotic directions of approach for particles arriving with zenith angles of 0^{o} (vertical), 16^{o} and 32^{o} in the north-south and east-west geomagnetic azimuths are tabulated.

The asymptotic directions are specified by two angles, the asymptotic latitude (positive to the north), and the asymptotic longitude (measured eastward from the Greenwich Meridian).. Computation errors are less than $\pm$ 0.1 degree.

The following symbols have been used in the tables:

XF Failed to complete integration: this indicates a very complex trajectory.

XR A trajectory which intersects the surface of the earth before arriving at the point of interest.

TABLE 4

COSMIC RAY VARIATIONAL COEFFICIENTS

In the following pages are tabulated the cosmic ray variational coefficients for 78 different stations and for 10 values of β, the exponent of the spectrum of variation, from $\beta = +0.6$ to $\beta = -1.5$. At the end of each table, the relative amplitude ($\alpha_m B_m$) and the correction for the geomagnetic bending ($\frac{\gamma_m - mL}{15m}$) for each value of β for each station are listed.

As derived in Part II, the observed local time of maximum of the mth harmonic of any anisotropy at a given station is given by

$$t_m = \frac{180m + m\ C_m - (\gamma_m - mL)}{15m} \quad \text{hours}$$

$$= \frac{C_m}{15m} + 12 - K$$

where $K = \frac{\gamma_m - mL}{15m}$ is the correction for the geomagnetic bending.

The value of K in hours for each value of β, for both the first and second harmonics, is listed in the table as "phase (in hours)".
