SUMMARY

The 1963-1965 evaluation in the Pensacola Thousand Aviator Study was the third follow-up examination in a longitudinal study of 1056 Naval aviators. The original study was carried out in 1940, and subsequent examinations were performed in 1951 and 1957.

During the 1963 examination, a large body of physiological, psychological, and personal history data was collected on 675 surviving members of the original population. Because of the magnitude and diversity of this information, an over-all view of distributions and interrelationships seems necessary for 1) providing assistance in understanding the findings of the study, and 2) indicating possible areas of further research by facilitating the discovery of relationships not otherwise apparent.

This report describes in detail the distributions and intercorrelations of 100 variables selected from the measures obtained during the 1963 follow-up examination. Data are presented in the form of descriptive statistics, frequency histograms, and Pearson correlation coefficients. Comments deal exclusively with statistical considerations, and no interpretations are attempted.

## ACKNOWLEDGMENTS

The authors are indebted to Mrs. Margaret Duty for her suggestions and assistance in compiling the data, and to Mrs. Alice Garman for her patience in typing the tables and charts. LT Robert J. Wherry, Jr., MSC, USN, prepared many of the programs necessary for analysis of the material; Mr. Richard Irons and Miss Mary Ann Overman aided in processing the data; Dr. Albert Damon evaluated the somatotypes; and Dr. Harlow Ades interpreted the electroencephalograms.

The Pensacola Study of Naval Aviators, popularly known as the Thousand Aviator Study, began in 1940 when 1056 student aviators and flight instructors were examined on a variety of physiological and psychological parameters. This longitudinal study has been continued with follow-up examinations in 1951, 1957, and 1963, the latter being the most comprehensive examination to date.

Data described in this report are based on the most recent examination, in which 675 members of the Thousand Aviator group were evaluated in Pensacola. These men ranged in age from 42 to 62 with a mean age of 47 . There were 798 survivors of the original group; four could not be located; 31 did not reply to inquiries; and the remaining 88 returned questionnaires but had not been examined at the time this report was prepared.

Data from the Thousand Aviator Study merit special attention for several reasons. First, the original population was young, healthy, and remarkably homogeneous. Furthermore, 1) the spectrum of data gathered is somewhat wider than that of similar studies; 2) all nonstandardized procedures have been carried out by only two investigators, providing a high degree of reliability; and 3) the laboratory data represent an exceptionally large collection of fasting serum specimens from a free-living, nonhospital population.

With the ever-increasing demands for knowledge concerning the relationships among variables considered important in the pathogenesis of coronary heart disease and related circulatory disorders, such a large-scale longitudinal study as that of the Thousand Aviators may provide at least a beginning toward answers to some of these demands. An awareness of the interrelationships of such factors as cholesterol, blood pressure, and body weight is potentially important not only in the development of control measures for coronary heart disease, but also in the application and interpretation of these measures.

These considerations, combined with the opportunity for perspective gained from an over-all examination of large numbers of related variables, make desirable a detailed statistical description of the information obtained from this group of middle-aged males. The variables are described in terms of distributional statistics and correlation coefficients. It is hoped that these descriptions will be of interest for exploration of relationships not previously apparent, as a reference source for comparative purposes, and for better understanding of other analyses based on data from the Thousand Aviators. The findings are presented only as reference information; comments on possible interpretations are withheld. Subsequent reports will deal with selected aspects of this longitudinal investigation.

## VARIABLES AND SUBJECTS

With rare exception, each of the 675 examined men underwent all tests and procedures. A slight variation in number of subjects for each variable is attributable either to some subjects who missed procedures because of scheduling difficulties or equipment breakdown, or to the nonavailability of technically satisfactory records. For these reasons $N$ 's on the variables range from a low of 627 to a high of 649. Descriptive statistics are based on all subjects available for each variable. The correlations, however, utilize only those subjects for whom complete data on all variables are available; hence, in nearly all cases, the N associated with the correlations is 600.

During the 1963-1965 follow-up examination, measures were obtained on a large number of variables from a variety of areas, including laboratory data, clinical examination, and anthropometric measurement. From these data, 100 variables were selected for detailed description on the basis of relevance and general interest. For each variable, the following information is reported: Mean,standard deviation, skewness, kurtosis, range, frequency distribution histogram, and correlations between that variable and all other variables.

Subsequent sections of this monograph deal with more detailed description of these statis:ics (Analysis of Data) and with brief definitions of the variables (Description of Variables). The tests and procedures followed in all four examinations are described fully in a recent publication (16).

## ANALYSIS OF DATA

Descriptive measures are reported in Appendix A by variable, while Appendix B gives a summary of means and standard deviations for all variables. Of the statistics reported, the mean, standard deviation, and range are relatively self-explanatory; each of the other statistics is discussed briefly in the following paragraphs. It should be recognized that for some of the variables reported, the descriptive statistics do not have their usual meaning. For dichotomies and coded variables, such as coronary heart disease, fundus, and arcus senilis, the standard deviation, skewness, and kurtosis cannot be interpreted in the same way as corresponding values for a continuous multi-valued variable. The same qualification applies to converted variables such as glucose which have been forced into a rectangular distribution by conversion on the basis of percentiles. These variables are important primarily for their correlations, since the descriptive statistics provide little information that can be generalized to other populations.

## SKEWNESS

The skewness measure is essentially an indication of the symmetry of the distribution of a variable about $i$ ts mean. The degree to which skewness ( $\sqrt{\beta_{1}}$ ) differs from zero is a measure of the extent to which there are extreme values in one direction or the other.

The skewness of the standard normal curve is 0.0 . A negative skew is associated with extreme values at the lower end of the distribution, and positive skew with extremes at the upper end.

## KURTOSIS

Kurtosis $\left(\beta_{2}-3\right)$ is a measure of the extent to which values of a distribution tend to be either centrally clustered about the mean or spread out over the entire range. The standard normal curve has a kurtosis of 0.0. Negative kurtosis indicates that the distribution tends toward flatness (the kurtosis of a perfectly rectangular distribution is -1.20 ), and positive kurtosis indicates a clustering of values around the mean.

For mathematical definitions and further discussion of skewness and kurtosis, the reader may refer to McNemar (14).

## FREQUENCY DISTRIBUTION HISTOGRAMS

For each score interval on the histograms, the frequency in that interval is given ( N column), together with the percentage of the total population falling in that interval (PCNT), and the cumulative proportion of the population falling in that interval and all lower intervals (CUMM).

Each "X" represents $1 / 50$ th (.02) of the modal frequency. Thus, if the interval with the largest number of cases has an $N$ of 50 , each $X$ in the histogram will represent a frequency of one; if the modal frequency is 150 , each $X$ represents three cases. The interval in which the modal frequency is found will always have $50 \mathrm{X}^{\prime} \mathrm{s}$, and each of the other intervals will have X's proportional to the modal interval. An interval may contain cases but have no plotted $X$ if its frequency is less than .02 of the modal frequency.

Medians may be determined from the histograms by obtaining from the CUMM column the 50 th percentile of the variable, that value below which 50 per cent of the measures lie.

## CORRELATIONS

All correlations are Pearson product-moment $r$ 's. The number of subjects associated with the correlations ranges from 600 to 644 , with the majority of the $r$ 's having $N$ 's of 600. For correlations based on a large number of subjects, a slight increase in $N$ will have little effect on the standard error of $r$, and the test of significance for $r$ based on 600 cases involves negligible error when used on the few correlations whose N is greater than 600. Hence the following two-tailed significance values may be used for all $\underline{r}$ 's with little loss of efficiency:

$$
r .05=.080 ; r .025=.091 ; r .01=.113 ; r .001=.135 ; r .0001=.159
$$

When large numbers of correlations are tested for significance, some caution is necessary in interpretation to avoid overcapitalization on chance relationships. With 100 variables ( 4950 correlations), almost 250 correlations would be expected to exceed the .05 level of significance on the basis of chance alone. For this reason it is recommended that a high level of significance (. 01 or ,001) be used in interpretation of the correlations. For convenience in reading the tables of $r$ 's all values of $r$ greater than or equal to .100 are given in heavier type. This represents approximately the .015 level of significance.

An additional point in interpretation of significance arises from the presence of artifact correlations. Some variables, such as basal and casual blood pressures, are obviously related to one another by virtue of being measures of essentially the same thing. Other variables are spuriously correlated because one may be a component of the other, as in the use of skinfold measures to compute body fat, or body diameters to compute lean body mass. An inspection of the definitions in the Description of Variables section will indicate those variables for which such a condition exists.

In addition to the above qualifications, other factors should be kept in mind in examining the correlations. The original Thousand Aviator group was a highly-selected population, all of whom had qualified for flight training by passing rigorous medical and flight aptitude examinations. While the relatively narrow age range and initial health and homogeneity of the group hold constant many difficult-to-control biological, social, and psychological parameters, this preselection also introduces certain difficulties. Restriction of range on many variables and consequent lack of extreme values may substantially reduce the size of the correlations between restricted variables. This restriction may be even further exaggerated in that the sample for this study, though large, represents only those subjects who were able to travel to Pensacola for the examination, perhaps the healthier and more uniform portion of the population. Likewise, generalizations from a group of uniform composition to the population at large may require caution. It is likely, however, that relationships among variables in a preselected initially healthy group like the Thousand Aviators may be extended to the total population of middle-aged men with considerably greater confidence than results obtained from groups selected for possession of some abnormality. In the case of the Thousand Aviators, it is the extremes, or abnormals, that are missing; in the latter situation, restriction of range is due to a scarcity of normals in the sample.

A further qualification concerns the fact that, when $N$ is large, very small correlations may show statistical significance but have no really practical application. A correlation of . 10 , while almost certainly representing a nonchance association between variables, indicates that the variables share only one per cent (.01) of their variances. Such correlations are of little predictive utility. They may, however, be quite valuable as a guide to the direction of future research and more intensive investigation of the indicated relationships.

It should further be recognized that the Pearson $r$ is a measure of linear relationship. If the change in units of one variable is not a constant function of the change in units of the other, regression will not be linear, and $r$ will be small or zero. While investigation of curvilinear relationships is beyond the scope of this report, the reader should be aware that failure to demonstrate a linear relationship need not preclude the presence of another form of association between the variables concerned.

## DESCRIPTION OF VARIABLES

1*. Age: Age in years at the time of subject's last birthday.
Blood pressures--Initial blood pressures were obtained after the fasting subject rested in a quiet room. Shortly thereafter the supine blood pressure was recorded from the right arm with a Bauman sphygmomanometer from which the back had been cut so that the column of mercury was visible from front and back. The examiner ascertained the systolic and fourth phase diastolic pressures viewing the mercury column from the unmarked side; at the appropriate time he signalled verbally to another observer who recorded the reading in mm Hg . The procedure was then repeated for the sitting blood pressures. In addition to the "basal" blood pressures, routine "casual" supine and sitting blood pressures were taken during the course of the physical examination.
2. Systolic blood pressure supine, basal
3. Diastolic blood pressure supine, basal
4. Systolic blood pressure sitting, basal
5. Diastolic blood pressure sitting, basal
6. Systolic blood pressure supine, casual
7. Diastolic blood pressure supine, casual
8. Systolic blood pressure sitting, casual
9. Diastolic blood pressure sitting, casual
10. Pulse pressure, supine: The difference in mm Hg between the basal systolic and diastolic blood pressures, supine position.
11. Pulse pressure, sitting: The difference in mm Hg between the basal systolic and diastolic blood pressures, sitting position.
12. Arcus senilis: Presence coded as 1 ; absence coded as 2.
13. Fundus: A Keith-Wagner classification (2), recorded as follows:

| Grade | Code |
| :---: | :---: |
| Normal | 1 |
| 1 | 2 |
| 2 | 3 |
| 3 | 4 |
| 4 | 5 |

*Arabic numbers preceding variable indicate number of that variable in appendices.
14. Hematocrit: Recorded as percentage of RBC by volume.
15. White blood count: Recorded as thousands per cubic millimeter.
16. Protein-bound iodine: Fasting value recorded in micrograms per cent (8).

Glucose-- Because of a difference in the laboratory procedure used initially from that used later in the study, all glucose values were converted to a linear coded scale according to percentile. The group was divided into the first 384 subjects (1) and the last 291 subjects (II), for whom laboratory procedures differed, and then separated at every sixth percentile. The final code was as follows:
$\left.\begin{array}{ccccc}\begin{array}{c}\text { Group I } \\ \text { Value (mg\%) }\end{array} & & & \begin{array}{c}\text { Group II } \\ \text { Code }\end{array} & \end{array} \begin{array}{c}\text { Value (mg\%) }\end{array}\right)$
17. Glucose, fasting: Coded value for fasting specimen of blood glucose (19).
18. Glucose, two-hour post-prandial: Coded value for blood sugar (19) obtained two hours after ingestion of 100 grams of glucose.
19. Cholesterol: Fasting value recorded in milligrams per cent (1).
20. Calculated cholesterol: Cholesterol calculated from the lipoprotein fractions employing estimated percentages in each $\mathrm{S}_{\mathrm{f}}$ fraction (17). This is the sum of $S_{f}$ value times percentage cholesterol for $S_{f}$ fractions $0-12,12-20$, and 20-400.

| Fraction | Value | Percentage Cholesterol | Cholesterol Fraction |
| :---: | :---: | :---: | :---: |
| 0-12 | ${ }^{1}$ | 0.458 | 0.458 X |
| 12-20 | $\times 2$ | 0.383 | $0.383{ }^{1}$ |
| 20-400 | $\mathrm{x}_{3}$ | 0.214 | $0.214{ }^{2}$ |

Calculated cholesterol $(\mathrm{mg} \%)=0.458 \mathrm{X}_{1}+0.383 \mathrm{X}_{2}+0.214 \mathrm{X}_{3}$
21. Calculated triglycerides: Triglycerides calculated from the lipoprotein fractions (17) in the same manner as the cholesterol above, but with appropriate percentages.
Calculated triglyceride $(\mathrm{mg} \%)=0.103 \mathrm{X}_{1}+0.258 \mathrm{X}_{2}+0.521 \mathrm{X}_{3}$
22. Uric acid: Fasting, recorded in milligrams per cent (4).
23. Lipoprotein 0-12: Lipoprotein subclass with flotation rates between $\mathrm{S}_{\mathrm{f}} \mathrm{O}$ and $\mathrm{S}_{\mathrm{f}} 12$ expressed in milligrams per cent (9).
24. Log lipoprotein 12-20*: Lipoprotein subclass with flotation rates between 12 and 20 whose value ( $\mathrm{mg} \%$ ) is given as a natural logarithm (9).
25. Log lipoprotein 20-400*: Lipoprotein subclass with flotation rates between 20 and 400, given as a natural logarithm (9).
26. Log atherogenic index*: This is a weighted value for coronary heart disease, derived from the two low-density lipoprotein subclasses, $\mathrm{S}_{\mathrm{f}} 0-12$ and $\mathrm{S}_{\mathrm{f}} 12-400$. The atherogenic index, formulated by Gofman et al. (10), is as follows:

$$
\text { A.I. }=\frac{m g \% S_{f} 0-12+1.75\left(\mathrm{mg} \% \mathrm{~S}_{\mathrm{f}} 12-400\right)}{10}
$$

27. Height standing: Maximum height to nearest tenth of an inch, measured under deep inspiration with head oriented in the Frankfort plane and back flat against a support.
28. Height sitting: Taken in same manner as standing height except with subject seated.
29. Weight: Weight to nearest pound was determined on a calibrated balance.

Skinfolds-- Four areas were measured: 1) midway between the right acromial process and the olecranon, 2) at the inferior angle of the right scapula, 3) the right mid-axillary line at the level of the xiphoid, and 4) the right mid-axillary line at the level of the umbilicus. A full fold of skin and subcutaneous tissue was pinched up from the underlying muscle parallel to the natural cleavage of the skin. Lange skinfold calipers were then applied to the fold about one centimeter below the fingers and halfway down the fold. Values were recorded to the nearest 0.5 millimeter after the indicator had settled.

> 30. Skinfold arm 31. Skinfold back 33. Skinfold chest

Circumferences-- All unilateral anthropometric values were obtained from the right side of the body. These measurements were taken at the fourth intercostal space with flexible steel tape, applying minimal pressure. Values were recorded to the nearest centimeter.
*These variables more closely approximated a normal distribution when values were ex-
pressed as natural logarithms. Conversion was made by the equation $f(X)=\log _{e}(X+1)$.
34. Chest circumference mid-breath: Chest circumference during tidal breathing.
35. Chest circumference inspiration: Chest circumference at maximal inspiration.
36. Chest circumference expiration: Chest circumference at maximal expiration.
37. Chest expansion: Difference between maximal inspiration and forced expiration.
38. Abdominal circumference: The relaxed abdomen was measured at the level of the umbilicus just superior to the "fat roll."

Biceps circumferences were assessed at the midpoint of the arm between the right acromial process and olecranon.
39. Biceps resting: Arm hung loosely at side.
40. Biceps contracted: Arm horizontal and forearm flexed with the fist tightly clenched.
41. Calf circumference: Maximal value while the subject stood on a chair with his legs slightly apart.

Diameters were measured with an anthropometer to the nearest millimeter with firm pressure on bony prominences. Chest diameters were measured at the level of the nipple during normal breathing.
42. Biacromial diameter: Subject stood with head bent slightly forward and shoulders "slouched." Measurement was made from the most lateral aspects of the acromial process.
43. Chest breadth: Maximal width with subject's arms at his sides.
44. Chest anterior-posterior diameter: Maximal anterior-posterior diameter with subject's arms at his sides.
45. Bi-iliac diameter: This measurement was made just inferior to the anterior superior iliac spine in the horizontal plane, with the legs together.
46. Wrist diameter: Breadth of wrist from the styloid process of the radius to that of the ulna with hand open and parallel to the sagittal plane.
47. Ankle diameter: Maximal diameter between maleoli with subject standing on a chair. Anthropometer blades were held 45 degrees down from the horizontal plane.
48. Ponderal index: Height (inches) divided by the cube root of weight (pounds).
49. Relative weight: Actual weight divided by standard reference weight for individuals of same age and height (7), multiplied by 100.
50. Body fat: Percentage of body fat was calculated from Grande's formula (5), $F=(4.0439 /$ density $)-3.6266$. Density was obtained from the equation ( 6 ), $D=1.0967-0.000315$ Back Skinfold (mm) - 0.000393 Chest Skinfold (mm) -0.000598 Arm Skinfold (mm) - 0.000170 Relative Weight (per cent).
51. Lean body mass: This parameter was derived from an equation supplied by Behnke (3):

$$
\text { LBM }=\left(\frac{\text { Sum diameters }}{28}\right)^{2} \times(\text { Height })^{0.7} \times 0.263
$$

where:

$$
\begin{aligned}
\text { Sum Diameters }= & \text { Biacromial }+ \text { Chest Breadth }+ \text { Bi-iliac }+ \\
& \text { Bitrochanteric }+2 \text { (Wrist) }+2 \text { (Ankle) }
\end{aligned}
$$

It may be considered the weight (in kilograms) of the fat-free body with the exception of a constant percentage ( $2.3 \%$ ) of essential lipids in bone marrow, the central nervous system, and other organs.

Somatotype-- Each subject was photographed and evaluated in the standard manner for somatotype by the anthroscopic method (18). Each of the three somatotypes was rated to the nearest half unit on a one to seven point scale.
52. Endomorphy: Dominance of visceral structures or soft roundness of body regions.
53. Mesomorphy: Athletic type of build or dominance of bone and muscle.
54. Ectomorphy: Presence of linearity, delicacy, and fragility of body structure.
55. Dynamometer: Strength was estimated in both right and left hands with a dynamometer. The forearm was held parallel to the floor and at right angles to the arm. The maximal recording (kilograms) of either hand was used.

Teleoroentgenograms were made in standard fashion employing posterior-anterior, left Tateral, and anterior oblique views. Measurements of the films were carried out according to the scheme of Ungerleider (20).
56. Transverse diameter of the heart: Sum of the maximum projections to the right and left heart borders from the midline.
57. Deviation from predicted transverse: Actual value of transverse diameter divided by that predicted from weight and height.
58. Frontal area of heart: Area $\left(\mathrm{cm}^{2}\right)=(\Pi / 4) \cdot L \cdot B$ where $L=$ long diameter (junction of cardiac silhouette and vascular pedicle on right to apex on left), and $B=$ broad diameter (greatest diameter of cardiac shadow perpendicular to long diameter).
59. Deviation from predicted frontal area: Actual value of frontal area divided by frontal area predicted from weight and height.
60. Cardiothoracic index: Transverse diameter of heart divided by internal transverse diameter of chest, multiplied by 100.
61. Electroencephalographic interpretation: Clinical evaluation of electroencephalogram scored as 1) normal, 2) borderline, and 3) abnormal.
62. Vital capacity: Maximal volume in liters of gas that can be expired from the lungs after a maximal inspiration.
63. Inspiratory capacity: Maximal volume in liters of gas that can be inspired from the resting expiratory level.
64. Expiratory reserve: Maximal volume in liters of gas that can be exhaled from the end-expiratory level.
65. Ballistocardiogram: Ballistocardiographic abnormalities were graded from normal, 0 , to severe, 3 , using the criteria of Moss (15).
66. Coronary heart disease: Special criteria (16) were set up for establishing the diagnosis of coronary heart disease. These diagnoses, agreed upon by two observers, were categorized as none, indeterminate, possible, probable, and definite. The none, indeterminate, and possible categories were combined and assigned a value of 0 ; the probable and definite categories were assigned a value of 1.
67. Alcohol amount: Consumption of alcohol was coded on a seven-point scale as 1) never drink, 2) rarely drink, 3) drink once or twice each week, 4) one drink per day, 5) two or three drinks per day, 6) more than three drinks per day, and 7) problem with alcohol.
68. Social status: Index of social status utilized is the "short" form of McGuire and White (13). Weights were assigned to occupation, source of income, and education, and weighted scores summed to obtain social status.
69. Military status: All participants were divided into one or the other of two groups: 1) Civilian--those who resigned or were discharged from active duty. This included those who retained reserve commissions. Persons in this category were assigned a code of 0 . 2) Military--those still on active duty or retired either after more than 20 years service or because of medical disabilities. This category was assigned a value of 1.
70. Cigarette amount: Amount of cigarette smoking was coded on a five-point scale as 1) nonsmokers of cigarettes, 2) 1-19 cigarettes per day, 3) 20 cigarettes per day, 4) 21-39 cigarettes per day, and 5) 40 or more cigarettes per day. For this analysis, smokers of pipes and cigars only were classified as nonsmokers.
71. Cigarette years: Duration of smoking of cigarettes was coded on a fivepoint scale as 1) nonsmokers, 2) 1 to 10 years, 3) 11 to 20 years, 4) 21 to 25 years, and 5 ) more than 25 years of cigarette smoking.
72. Flying years: Number of years flown as a pilot or crew member, military or civilian aircraft.

Guilford-Zimmerman Temperament Survey-- The GZTS is a "paper and pencil" personality questionnaire in which the subject answers 300 questions about himself with a yes, no, or ? reply. Scores are obtained on the following ten scales. (Further elaboration of scale definitions is given in the GZTS instruction manual (11).)
73. G scale: General Activity
74. R scale: Restraint
75. A scale: Ascendance
76. S scale: Sociability
77. E scale: Emotional Stability
78. O scale: Objectivity
79. Fscale: Friendliness
80. T scale: Thoughtfulness
81. P scale: Personal Relations
82. M scale: Masculinity

Electrocardiographic Variables.
83. Heart rate: Resting heart rate (average lead $I$ and lead $V_{6}$ ) during the fasting electrocardiogram.
84. Heart rate immediately after exercise: Heart rate (average lead I and lead $V_{6}$ ) after 3 minutes of exercise on the modified Harvard Step Tes $\dagger$ at a rafe of 20 steps per minute.
85. PR interval: Maximal PR interval (21) in hundredths of a second (standard leads I, II, and III) in the fasting electrocardiogram.
86. QRS duration: Maximal QRS duration (21) in hundredths of a second in the fasting electrocardiogram using standard leads.
87. QRS frontal vector: The heading in degrees of the mean QRS frontal vector was calculated from the algebraic sum of leads I and III, utilizing the table compiled by Jackson and Winsor (12).
88. T frontal vector: The heading in degrees of the mean $T$ frontal vector obtained in a manner analogous to the QRS vector.
89. QRS-T angle frontal plane: The absolute degrees difference was obtained by algebraically subtracting the $T$ frontal vector from the QRS frontal vector.
90. Sigma QRS: The absolute sum in millimeters of the $Q, R$, and $S$ deflections in leads I, II, and III.
91. Sigma $T$ : The absolute sum in millimeters of the $T$ deflection in leads 1 , II, and III.
92. Maximal QRS voltage frontal plane: The largest amplitude in millimeters of any component of the QRS complex in the frontal plane.
93. Maximal QRS deflection frontal plane: The largest peak to peak deflection ( $R$ wave to $Q$ or $S$ wave) in millimeters of any complex in the frontal plane.
94. Amplitude $T(1)$ : Amplitude of the $T$ wave in millimeters measured in lead I of the fasting electrocardiogram.
95. Ratio $T(I) / R(1)$ : $T$ wave ( mm ) divided by $R$ wave ( mm ) in lead $I$ of the fasting electrocardiogram.
96. Amplitude $S(I)+S(I I)+S(I I I)$ : The sum in millimeters of the $S$ waves in leads I, II, and III.
97. Amplitude $S\left(V_{1}\right)+R\left(V_{5}\right.$ or $\left.V_{6}\right)$ : The sum in millimeters of the $S$ wave in lead $V_{1}$, and the greater of the two $R$ waves in lead $V_{5}$ or $V_{6}$.

The following electrocardiographic variables were obtained after exercise for three minutes at 20 steps per minute on the modified Harvard Step Test. Leads $\mathrm{V}_{4}$ through $\mathrm{V}_{6}$ were used for measurement for a period of five minutes after exercise. The procedure for obtaining these points or areas has been outlined in the monograph on methodology (16).
98. Maximal $Z$ after exercise: The most negative nonjunctional point on the ST segment.
99. Maximal J-ST after exercise: Largest area of ST depression from the isoelectric line after exercise, expressed in square millimeters.
100. Maximal ST after exercise: Largest area $\left(\mathrm{mm}^{2}\right)$ of nonjunctional ST depression from the isoelectric line after exercise.
