ABSTRACT

A computer program is presented to solve the heat conduction equation for boundary conditions appropriate to the lunar surface during an eclipse and during a lunation. This program allows for very general representations of the temperature- and depth-dependent thermal properties in a multilayer model. Both infrared and microwave brightness temperatures may be predicted for the Moon and similar rotating bodies in which thermal conduction and radiative transfer are the most significant forms of energy transport near the surface.

I. INTRODUCTION

Since the classic studies of thermal conduction beneath the lunar surface, made by Wesselink (1948) and by Piddington and Minnett (1949), interest in this problem has been stimulated by detailed observations made possible by advances in instrumentation, and by the expectation of directly investigating the lunar surface itself. Because thermal conduction may, under certain astrophysical conditions, play an important role in energy transport, its basic equations have been applied to studies of the Martian surface by Sinton and Strong (1960), to the solar corona, and to the planet Mercury. As the result of the accumulation of more detailed infrared and microwave data, it has become important to solve the problem of thermal conduction beneath the lunar surface for less-idealized models than present analytical methods allow. A computer program has therefore been written to compute infrared and microwave brightness temperatures during both an eclipse and a lunation for very general assumed thermal properties and surface structures.

The simplest model of the lunar surface consists of a homogeneous plane-parallel medium with temperature- and depth-independent thermal properties. Although this model lends itself readily to analytical solution, Piddington and Minnett (1949) and Jaeger and Harper (1950) first showed its inconsistency with the data, and suggested that less-idealized models are necessary. More recently, several analytical solutions have been obtained for microwave brightness temperatures directly, rather than for their lowest Fourier harmonics. Such exact solutions are necessary to interpret increasingly refined millimeter wave observations. Using Fourier techniques, Muncey (1958, 1963) has derived both infrared and microwave temperatures for the case of thermal properties linearly dependent on temperature in a homogeneous medium with a plane boundary. Copeland (1965) has obtained analytical expressions for the microwave radiation from a two-layer model with temperature-independent thermal properties. Also using Laplace transform techniques, Bhatnagar (1965) has solved the problem, including radiative conductivity, for a material whose density is allowed to vary smoothly with depth. Unfortunately, the complexity of these solutions for the simple cases under consideration strongly suggests that for more realistic geometrical structures and temperaturedependent thermal properties, including the simulation of radiative transfer in the medium, this problem may not be amenable to analytical solution.

Rewriting the heat conduction equation in terms of finite differences permits numerical solutions of a much larger class of problems. These problems include calculations of infrared brightness temperatures on the basis of two-layer models by Jaeger and Harper (1950), models with temperature-dependent thermal properties by Watson (1961), and models including both complications by Ingrao, Young and Linsky (1965)^{*}.

Ideally, one desires a computing scheme which predicts both infrared and microwave brightness temperatures during an eclipse and a lunation for postulated lunar materials with arbitrarily temperatureand depth-dependent thermal and electric properties. Such a scheme must be numerical, but should not be unnecessarily limited by either the approximations inherent in the finiteness of the differences or by the analytical representations of the material parameters allowed. In addition, if this computing scheme closely simulates the actual physical situation, one could readily alter the representation of these parameters and the boundary conditions imposed. Thus the ability to adequately solve more refined lunar conduction problems would be limited by the suitability of the model itself, and not by the difficulty of devising a new numerical solution.

The present scheme, a generalization of that used in Paper I, is an attempt to incorporate each of these features with a minimum waste of computation time. The scheme has been written in FORTRAN II, which, with certain nonstandard subroutines as noted below, should be compatible with any IBM 7090 or 7094 system. We will describe how each part of the program operates and will note the modifications that can be made to take into account other forms of energy transport or different representations of the thermal or electromagnetic properties.

Hereafter referred to as Paper I.

-2-

II. BASIC EQUATIONS

With the assumption of a plane-parallel geometry, the heat conduction equation is of the form:

$$\rho c(\mathbf{x}, \mathbf{T}) \quad \frac{\partial \mathbf{T}}{\partial t} = \frac{\partial}{\partial \mathbf{x}} \left[\mathbf{k}(\mathbf{x}, \mathbf{T}) \quad \frac{\partial \mathbf{T}}{\partial \mathbf{x}} \right] + Q(\mathbf{x}, t) \tag{1}$$

where

The source term Q(x,t) could arise from absorbed solar radiation in a partially transparent medium, as considered by Buettner (1963), or from radioactive decay. Eq. (1) may be written in terms of finite differences as

$$\rho c(\mathbf{x}, \mathbf{T}) \quad \frac{\partial \mathbf{T}}{\partial \mathbf{t}} = \frac{\begin{bmatrix} \mathbf{k} (\mathbf{x}, \mathbf{T}) & \frac{\partial \mathbf{T}}{\partial \mathbf{x}} \end{bmatrix}_{\mathbf{x}} + \frac{\Delta \mathbf{x}}{2}}{\Delta \mathbf{x}} - \begin{bmatrix} \mathbf{k} (\mathbf{x}, \mathbf{T}) & \frac{\partial \mathbf{T}}{\partial \mathbf{x}} \end{bmatrix}_{\mathbf{x}} - \frac{\Delta \mathbf{x}}{2}}{2} + Q(\mathbf{x}, \mathbf{t}) \quad . \tag{2}$$

In this program the medium is divided into six layers, each consisting of an arbitrary number of sublayers or depth integration steps. A continuous depth dependence of $\rho c(x,T)$ and k(x,T)may be approximated by specifying their values or their parameters in these six or more layers. One may specify different values of the depth integration step Δx in each layer to allow, for example, a more accurate representation of the temperature distribution near the surface where large temperature gradients exist. At the boundary of two layers we take such changes of the integration step into account.

The program considers explicitly three models of the lunar surface material, in each of which Q(x,t) is assumed to be zero.

- $\underbrace{Model 1}_{c(x,T)} = c(x)$ k(x,T) = k(x)
- $\underbrace{Model 2}_{k(x,T)} = c(x)$ $k(x,T) = k(x) + 4 \overline{\epsilon_M} \sigma T^3 (x) s(x)$

where $\overline{\epsilon_M}$ and s(x), as defined more fully in Paper I, are the radiant infrared emissivity and effective mean spacing of radiating surfaces.

<u>Model 3</u> Linearly temperature-dependent properties $c(x,T) = c_{O}(x)T$ $k(x,T) = k_{O}(x)T$.

Using forward and central differences and writing the temperature at a time $n(\Delta t)$ and depth $m(\Delta x)$ as T_m^n , one may write the heat conductivity equation in a layer as follows:

Models 1 and 2

$$T_{m}^{n} = T_{m}^{n-1} + A_{L} \left\{ \left[K_{L} + 4 \overline{\epsilon}_{M} \sigma s_{L} (T_{m}^{n-1})^{3} \right] \left[T_{m+1}^{n-1} - 2 T_{m}^{n-1} + T_{m-1}^{n-1} \right] + \left[3 \overline{\epsilon}_{M} \rho s_{L} (T_{m}^{n-1})^{2} \right] \left[(T_{m+1}^{n-1})^{2} - 2 T_{m+1}^{n-1} T_{m-1}^{n-1} + (T_{m-1}^{n-1})^{2} \right] \right\}, \quad (3)$$

where

$$A_{L} = \frac{\Delta t}{\rho_{L} c_{L} (\Delta x)_{L}}$$

Model 3

$$T_{m}^{n} = T_{m}^{n-1} + A_{L} \left\{ (T_{m+1}^{n-1} - 2T_{m}^{n-1} + T_{m-1}^{n-1}) + \frac{1}{4T_{m}^{n-1}} \left[(T_{m+1}^{n-1})^{2} - 2T_{m+1}^{n-1} T_{m-1}^{n-1} + (T_{m-1}^{n-1})^{2} \right] \right\}, \quad (4)$$

where

$$A_{L} = \left(\frac{k_{o}}{\rho c_{o}}\right) \frac{\Delta t}{(\Delta x)^{2}}$$

At the boundary of two layers, L and L+1, Eq. (2) may be written as:

$$\frac{\text{Models 1 and 2}}{T_{m}^{n} = T_{m}^{n-1} + B} \left\{ \left[K_{L+1} + 4\overline{\epsilon}_{M}\sigma s_{L+1} + \left(\frac{T_{m+1}^{n-1} + T_{m}^{n-1}}{2} \right)^{3} \right] \left[\frac{T_{m+1}^{n-1} - T_{m}^{n-1}}{(\Delta x)_{L+1}} \right] - \left[K_{L} + 4\overline{\epsilon}_{M}\sigma s_{L} + \left(\frac{T_{m}^{n-1} + T_{m-1}^{n-1}}{2} \right)^{3} \right] \left[\frac{T_{m}^{n-1} - T_{m-1}^{n-1}}{(\Delta x)_{L}} \right] \right\} , \qquad (5)$$

where

$$B = \frac{4(\Delta t)}{(\rho_{L}c_{L} + \rho_{L+1}c_{L+1}) \left[(\Delta x)_{L} + (\Delta x)_{L+1}\right]}$$

Model 3

$$T_{m}^{n} = T_{m}^{n-1} + \frac{B}{T_{m}^{n-1}} \left[k_{0, L+1} \left(\frac{T_{m+1}^{n-1} + T_{m}^{n-1}}{2} \right) \left(\frac{T_{m+1}^{n-1} - T_{m}^{n-1}}{(\Delta x)_{L}} \right) - k_{0, L} \left(\frac{T_{m}^{n-1} + T_{m-1}^{n-1}}{2} \right) \left(\frac{T_{m}^{n-1} - T_{m-1}^{n-1}}{(\Delta x)_{L}} \right) \right] , \qquad (6)$$
where

$$B = \frac{4(\Delta t)}{(\rho_L c_L + \rho_{L+1} c_{L+1}) \left[(\Delta x)_L + (\Delta x)_{L+1} \right]}$$

Other representations of c(x,T) and k(x,T), for example, by a power series in T or a tabular set of values, and the inclusion of source terms, may be readily accomplished by inserting difference equations similar to (3), (4), (5), and (6) in subroutine EXTRA. In addition, heat conductivity equations for different geometries, such as spherical geometry, can be taken into consideration in this manner.

The surface boundary condition at a position on the lunar surface with rectangular coordinates (ξ, η) may be written:

$$k(\mathbf{x},T)\left(\frac{\partial T}{\partial \mathbf{x}}\right)\mathbf{x}=0 = \overline{\epsilon}_{M}\sigma T_{S}^{4} - \overline{\epsilon}_{D}I(\xi,\eta,t) , \qquad (7)$$

where the insolation $I(\xi, \eta, t)$, when the **Sum** is above the horizon, is

$$I(\xi,\eta,t) = f(t)\sigma T_{S}^{4} \left[-\xi \sin \frac{2\pi t}{P} + \left(1 - \eta^{2} - \xi^{2} \right) \cos \left(\frac{2\pi T}{P} \right) \right] , \quad (8)$$

anđ

$$\overline{\epsilon}_{b} = 1 - A_{b}$$

where $\overline{\epsilon}_{b}$ = bolometric emissivity computed from the bolometric

- f(t) = reduction in insolation during penumbral eclipse

In computing the surface temperature $T_{o'}$, Newton's method is used to solve the equations:

$$^{K}_{1} \left[\frac{-T_{2}^{n} + 4T_{1}^{n} - 3T_{O}^{n}}{2(\Delta x)_{1}} \right] + 4 \overline{\epsilon}_{M} \sigma s_{1} \left[\frac{T_{1}^{n} + T_{O}^{n}}{2} \right]^{3} \left[\frac{T_{1}^{n} - T_{O}^{n}}{(\Delta x)_{1}} \right]$$
$$= \overline{\epsilon}_{M} \sigma (T_{O}^{n})^{4} - \overline{\epsilon}_{D} I(\xi, n, t) , \qquad (9)$$

Model 3

$$-k_{O}\left(\frac{T_{O}^{n}+T_{1}^{n}}{2}\right)\left[\frac{3T_{O}^{n}-4T_{1}^{n}+T_{2}^{n}}{2(\Delta x)_{1}}\right] = \overline{\epsilon}_{M^{O}}(T_{O}^{n})^{4} - \overline{\epsilon}_{b}I(\xi,n,t) \quad (10)$$

As in the case of the above heat conductivity equations, k(x,T) can be included by writing the corresponding difference equations in subroutine EXTRA. One could also consider a rough surface in a statistical manner here. As a lower boundary condition we have assumed the temperature to be a constant, but a constant-flux lower boundary condition can be specified by holding the temperatures constant at the two lowest depths.

Radio brightness temperatures $T_B(t)$ are evaluated from the temperature distributions T(x,t) in the Rayleigh-Jeans approximation by the equation

$$T_{S}(t) = (1-R) \left[a \sec \theta_{in} \int_{0}^{x \max} T(x,t) e^{-ax \sec \theta_{in}} dx + T(x_{\max},t) e^{-ax_{\max} \sec \theta_{in}} \right], \qquad (11)$$

where R = Fresnel reflection loss
 a = electromagnetic absorption coefficient;

the assumed form of, a, is

$$a = a_0 \lambda^{\mathbf{p}} \tag{12}$$

with a_0 and p, parameters. θ_{in} , the angle from the normal for a ray leaving the surface at the observer's zenith angle θ , is obtained from the index refraction, n, by use of Snell's law

$$\sin\theta = n\sin\theta_{in}$$
 (13)

Assuming negligible permeability and homogeneity of the lunar surface material, the Fresnel reflection loss at the surface for nonpolarized radiation is given by

$$R = \frac{1}{2} \left[\frac{\tan^2 (\theta_{in} - \theta)}{\tan^2 (\theta_{in} + \theta)} + \frac{\sin^2 (\theta_{in} - \theta)}{\sin^2 (\theta_{in} + \theta)} \right] .$$
(14)

Evaluation of $T_B(t)$ for a statistical distribution of slopes and the evaluation of its net polarization could be done by modifying this basic computation procedure.

III. COMPUTING PROCEDURE

The solution of Eqs.(3) - (10) to obtain the temperature distribution T(x,t) during an eclipse is performed by the MAIN Program, and during a lunation by subroutine MONTH. In addition, the subroutines SOLUX, STATIC, EXTRA and NOCAL are called by these programs to perform specific operations. The non-standard features, subroutines HYPLOT, ICE3, and GIOH, the REREAD version of (TSH) and the function FRENCH, will be discussed below.

A. MAIN Program

This program computes surface temperatures and temperature distributions beneath the surface during an eclipse, and serves as a central-control routine which reads in most of the data and supervises the logical flow of computation. If one wishes to compute temperatures based on an assumed temperature distribution beneath the surface prior to eclipse, one can read in these temperatures U(I,I), for each depth integration step I by means of the TEMPERATURES card described below. In general, one does not know what initial temperature distribution is appropriate, and errors of 5°K or more may occur in the surface temperature during eclipse, especially for multilayer models. Thus one should allow the assumed initial temperature distribution to relax over the course of a complete lunation and should use the resulting temperature distribution as the pre-eclipse distribution. This may be done automatically by putting NMONTH = 1, 2, or 3 and NECLIP = 1 on the CONTROL card described below.

The MAIN program initially reads in all the data it will use, as well as reading in all or part of the data used by subroutines MONTH, NOCAL, and STATIC. It then switches control to subroutine MONTH if a number of lunations are to be simulated first and assumes that the last temperature distribution computed there is the appropriate pre-eclipse distribution. The pre-eclipse insolation is computed from the local solar zenith angle and from the value of the assumed theoretical equilibrium blackbody-temperature (TEMAX) read in by subroutine MONTH. This irradiance is reduced during penumbral eclipse by the factor f(t) computed by subroutine SOLUX for the end of each integration step.

For each time integration step N, the temperature at a depth M, U(M,N), is computed first inside each layer according to Eqs.(3), (4), or an analogous equation in subroutine EXTRA. At each interlayer boundary depth K, U(K,N) is computed from Eqs.(5), (6), or substitute in EXTRA. This process is then continued throughout the penumbral and umbral phases of eclipse and as far into the succeeding penumbral and post-eclipse phases as is specified. At certain intervals of elapsed

-8-

time, determined by the value of TECLIP read in by subroutine STATIC, control is switched to STATIC for the evaluation of radio brightness temperatures, using the present temperature distribution for T(x,t) in Eq.(11). If, for the thermal parameters and values of Δt and Δx used, the difference equations become unstable, the program automatically decreases the value of Δt and restarts the eclipse simulation.

Finally, the program computes surface brightness temperatures for each five minutes of elapsed time, using subroutine NOCAL; computes, every thirty minutes, the ratio of these surface temperatures and the temperature distribution to the pre-eclipse surface temperature; and plots out and prints all these results.

To process efficiently the many kinds of data needed by this program, we have used the card rescanning feature of the REREAD version of subroutine (TSH) and the free-field G-type format of subroutine HUGIOH. The manner in which a card is to be read and the kind of data expected is determined by the first six letters of a code word at the beginning of the card. These cards need not be used in any special order, except that the CONTROL card must be last. When no card is read in, previous data are assumed. For each card or group of cards, we include the code word, its meaning, and the data expected on the card, in that order.

CODE WORD

1.	POSITION	 Specified position on lunar surface
	ETA	 Rectangular North-South coordinate
	XI	 Rectangular East-West coordinate
2.	ECLIPSE	 Photometric data and circumstances of eclipse
	E	 Mean infrared emissivity near wavelength of
		maximum emission
	EBOL	 Bolometric emissivity for solar irradiance
	TOE	 Duration of penumbral eclipse in seconds at (ξ,η)
	TIME	 Total duration of penumbral and umbral eclipse
		in seconds at (ξ,η)
	PEN	 Time past end of umbral phase in units of TOE to
		continue computation

-9-

3.	THERMAL		Specification of thermal properties
	LAYER		Data on this card pertain to this and all lower
			layers
	BV		Conductivity (cal cm ⁻¹ °K ⁻¹ sec ⁻¹)
	BR		Density (gm cm ⁻³)
	BC		Specific heat (cal gm ⁻³ °K ⁻¹)
	RAT		Ratio of radiative to conductive flux at 350°K.
			This is used to determine value of S(x)
	MODEL		Model number. If $MODEL = 4, 5, 6, or 7, then$
			MAIN and MONTH will use equations in subroutine
			EXTRA.
	Note:		If these parameters are to vary with depth,
			several cards are needed, one for each layer or
			adjacent layers with the same parameters. These
			cards must be in descending order according to
			depth.
4.	GAMMAS		Alternative method of specifying thermal
			properties subject to the same conditions as in
			the above Note.
LAYER,	RAT, MODEL		Same as before.
	GA		Thermal parameter (Κρc) ⁻²
			$(cal^{-1} cm^2 \circ K sec^{-\frac{1}{2}})$
			(assuming $\rho = 1 \text{ gm cm}^{-3}$ and $c = 0.2 \text{ cal gm}^{-3} \text{ sK}^{-1}$)
5.	DEPTHS		Depth integration data
	J(I)		Cumulative number of integration steps at the
			base of the ith layer (The surface is step 1.)
	X(I)		Length of integration steps in <u>I</u> th layer (cm).
6.	TEMPERATUR	ES	
	U(I, 1)		Initial temperature distribution if eclipse
			calculation is to be performed immediately.
			Ten temperatures per card in descending order of
			depth are expected. The surface is designated
			by $I = 1$.
7.	REDUCE		Data required by subroutine NOCAL described
			below.
8.	CONTROL		This card initiates computations of eclipse or
			lunation temperature distributions.

-10-

•

٠

NMONTH	= 0 No lunation.
	= 1 Lunation done after reading in initial tempera-
	ture distribution and other data in subroutine
	MONTH.
	= 2 Lunation done using previous initial tempera-
	ture distribution.
	= 3 Lunations done using temperature distribution
	at end of previous lunation computation.
NECLIP	= 0 No eclipse
	= 1 Simulate an eclipse after temperature distribution
	is relaxed during a lunation if called for.
LRADIO	= 0 No microwave brightness temperatures calculated.
	= 1 Calculate microwave brightness temperatures
	assuming unit microwave emissivity.
	= 2 (Subroutine STATIC called) Compute microwave
	brightness temperatures using previous electro-
	magnetic absorption parameters.
NSOLUX	= 0 Expect penumbral eclipse data in subroutine SOLUX.
	= 2 Don't expect this data.
т	= Time integration step (Δt) in seconds for the
	MAIN Program.
TMONTH	= Time integration step (Δ t) in seconds for sub-
	routine MONTH.

B. Subroutine MONTH

This subroutine performs the same kind of calculations as the MAIN Program except with the insolation computed for the lunar surface feature considered for different times during a month according to Eq. (8). If the value of NMONTH is 1, this subroutine reads in two sets of data in this order:

1.	TOL	 Duration of a month in units of a synodic month.
		(This allows for application to other planets
		or satellites rotating with different periods.)
	TIME	 Duration of integration in units of a synodic
		month.
	TEMAX	 The value of T_{S} in °K in Eq. (8).

-11-

These code symbols have the following meanings:

 UBEG(1) -- Initial temperature distribution in order of increasing depth with ten temperatures per card.

After a few checks to see whether the data are reasonable and that the computations will not be implausibly long, this subroutine uses the initial temperature distribution and the data read in by MAIN for the determination of subsequent surface temperatures and internal temperature distributions. Periodically, it also checks to see whether the equations are stable; if they are not, it restarts these computations with a smaller value of Δt . The integration in Eq. (11) for microwave temperatures is evaluated at intervals specified by the value of TIMER computed in subroutine STATIC. Every six hours it prints out the temperature distribution as well as the local zenith angle of the Sun, the surface brightness temperature, the elapsed time in hours, and the number of hours in darkness during nighttime. As further output, the program plots the interval temperature distribution every two days.

C. Subroutine STATIC

This subroutine performs the integral in Eq. (11) each time it is called, for several wavelengths and for several values of the electromagnetic absorption coefficient parameters. These data are read in when STATIC is first called by the MAIN Program, if LRADIO = 1, by two groups of cards. Each of these cards contains data for one case.

1.	FRACT	 Index of refraction.
	ABS	 Value of a in Eq. (12) (cm^{-1}) .
	POWER	 Exponent of the wavelength dependence
		of the absorption coefficient.
2.	TMON	 Interval of days during a lunation at which
		STATIC is called.
	WAVE	 Microwave wavelengths (cm) for evaluation of
		Eq. (11). Up to five wavelengths may be speci-
		fied. In this subroutine, reflections at the
		layer interfaces are ignored.

-12-

The integral is performed by the SHARE distributed subroutine ICE3, using parabolic interpolations of the present temperature distribution U(M,N) by function FRENCH. Near interlayer boundaries linear interpolations are used to allow for large changes in the depth integration step. After a full lunation has been simulated, the subroutine does a least squares analysis of the resulting brightness temperatures, obtaining the mean temperatures \overline{T}_B , amplitudes of the first harmonic A, and phase lags ϕ relative to insolation, in the equation

$$T_{\rm B} = \overline{T}_{\rm B} + A \cos\left(\frac{2 \pi t}{p} - \phi\right) \qquad (15)$$

D. Subroutine SOLUX

SOLUX computes values of f(t), the fractional insolation during the penumbral eclipse, by considering the geometrical area of the Sun occulted by the Moon and solar limb darkening. The latter data are read in as up to ten coefficients in the power series

$$I(x) = \sum_{i=1}^{10} A_i \sin^{(i-1)} \alpha .$$
 (16)

where α is the zenith angle of the Moon at a point on the Sun, and the parameters, A, are least square coefficients to limb darkening data I(α). We have used the values of I(α) at 6000 Å tabulated by Allen (1963).

E. Subroutine EXTRA

Alternative versions of the conductivity equations and surface boundary conditions will be used by the MAIN Program and by MONTH if added to this subroutine and the code symbol MODEL has the value 4, 5, 6, or 7. Up to four such sets of equations can be included.

F. Subroutine NOCAL

This subroutine reduces surface temperatures to brightness temperatures corresponding to a decrease in the emitted flux by the factor $(1-\overline{\epsilon}_{M})$. To do this, the data needed and read in by the MAIN Program consist of a number of blackbody surface temperatures DTDS, per one-percent decrease in irradiance detected in the infrared spectral interval under consideration.

IV. NON-STANDARD FEATURES IN THE PROGRAM

A. HUGIOH

A SHARE Distribution Agency subroutine (number 3330), written by Dr. Owen Gingerich of the Smithsonian Astrophysical Observatory, revises the regular version of the system library routine IOH to include a free-field G-format. In this format, numerical data are read in either as exponential, fixed, or floating-point numbers as specified by the variable name, and alphabetic characters are ignored. At least one blank space must separate one datum from another.

B. REREAD Version of (TSH)

This SHARE Distribution Agency subroutine (number 1497), also written by Dr. Gingerich, permits the multiple reading of data cards. Logically equivalent to the statement BACKSPACE N, where N is the input tape number, this subroutine stores the image of the data card immediately preceding the CALL REREAD statement for rescanning by the next READ INPUT TAPE statement. One may use the standard version of the system library subroutine (TSH) in the MAIN program by placing the code word on one card and the data on the subsequent one.

C. ICE3

This SHARE Distribution Agency subroutine (number 411) integrates an analytical expression or tabular set of data using a variable integration step to keep extrapolation errors within specified limits.

D. HYPLOT

This is a graph-plotting subroutine written by Dr. Andrew T. Young of Harvard College Observatory. Entry points are SET, LIMITS, REMARK, HOLLER, POINTS, GRID, and GRAPH. Copies of HYPLOT and FRENCH are available upon request from Jeffrey L. Linsky.

E. FRENCH

The function FRENCH, also written by Dr. Young, performs parabolic interpolation to a tabular set of data.

V. THE PROGRAMS

These programs have been thoroughly tested by the author for the conditions appropriate to the lunar surface and using the three models explicitly described above.

A listing of each of these programs and a typical set of data cards are included in the Appendix.

ACKNOWLEDGMENT

The author wishes to acknowledge the guidance of Hector C. Ingrao in many aspects of this work. The author would also like to thank Richard H. Munro for the original version of parts of this program and his unselfish assistance, and the Harvard University Astronomy Department for the allocation of computer time.

This work was sponsored by the National Aeronautics and Space Administration under Research Grant No. NsG 64-60.
