January 2004

Institutions and Agricultural Productivity in Sub-Saharan Africa[1]

Lilyan E. Fulginiti[a, 2], Richard K. Perrin[a], and Bingxin Yu[a]

[a] *Department of Agricultural Economics, University of Nebraska, Lincoln, NE 68583, USA*

Abstract: Agricultural productivity in 41 Sub-Saharan Africa (SSA) countries from 1960 to 1999 is examined by estimating a semi-nonparametric Fourier production frontier. Over the four decades the estimated rate of productivity change was 0.83% per year, although the average rate from 1985-99 was a strong 1.90% per year. Former UK colonies exhibited significantly higher productivity gains than others, while Liberia and countries that had been colonies of Portugal or Belgium exhibited net reductions in productivity. We measure a significant reduction in productivity during political conflicts and wars, and a significant increase in productivity among those countries with higher levels of political rights and civil liberties.

Key Words: Sub-Saharan Africa, agricultural productivity, institutions, stochastic frontier, Fourier functional form.

Introduction.

Sub-Saharan Africa is one of the world's poorest regions. Its population and land area are approximately three times that of the USA. The region's economies are heavily dependent on agriculture, which accounts for two-thirds of the labor force, 35% of GNP and 40% of foreign exchange earnings. Productivity performance in the agricultural sector is thus critical to

---

improvement in overall economic well-being in Sub-Saharan Africa (SSA), and it has therefore been the subject of at least seven multi-country studies (Block (1994), Frisvold and Ingram (1995), Thirtle, *et al.*(1995), Lusigi and Thirtle (1997), Rao and Coelli (1998), Chan-Kang *et al.* (1999), Suharyanto, *et al.*(2000) and FAO (2000).)   These studies, though they covered different time periods and different sets of SSA countries, have been reasonably consistent in reporting positive average productivity gains during the 1960's, regression or no gain in productivity during the 1970's, with a recovery to positive gains during the 1980's and early 1990's. The present study aims to provide a more comprehensive understanding of agricultural productivity growth in this region, and the potential role of colonial heritage and other institutional factors that might give additional insights on the differences between countries.

Analytical Approach.

Productivity is defined as output per unit of input. Productivity growth aims at capturing output growth not accounted for by growth in inputs.   We address two questions about agricultural productivity in SSA. First, what have been the rates of productivity growth? Second, what institutional and socio-political factors may have affected agricultural productivity performance in SSA in the last four decades?

Among the many alternatives available to estimate productivity growth, the one we adopt is the production function approach pioneered by Solow and Griliches and used by many others in the multi-country context. Aigner, Lovell and Schmidt and Meeusen and Van den Broeck modified the production function to allow for the presence of technical inefficiencies captured by a one-sided error term. This standard neoclassical production function is re-labeled a stochastic production frontier and following Battese and Coelli (1995) is written:

(1) $\ln Y_{it} = f(x_{it}, t; \beta) + v_{it} - u_{it}$ $i = 1, ..., I,\ t = 1, ..., T$

where Y_{it} is output of the *i*-th country in time period *t*, x_{it} is an *Nx1* vector of the logarithm of

inputs for the *i*-th country in time period *t*, β is a vector of unknown parameters, v_{it} are random

variables which are assumed to be iid $N(0, \sigma_v^2)$ and independent of u_{it}, and u_{it} is a non-negative

random variable distributed iid $N(\eta, \sigma_u^2)$ associated with technical inefficiency across production

units (or individual production units effects.) In our case, it accounts for heterogeneity across

countries that can cause departures from maximum potential output.

We use this production frontier to break down the growth rate of aggregate output into

contribution from the growth of inputs versus productivity change:

(2) $\dot{Y}_{it} = \sum_{n} \varepsilon_{itn} \dot{x}_{itn} + \dot{TFP}_{it}$

where a dot over a variable indicates its rate of change, and ε_{itn} is the production elasticity of

input *n*, for country *i* in year *t*, $\varepsilon_n = \dfrac{\partial f(x,t,\beta)}{\partial x_n}$. In turn, TFP growth can be decomposed as

(dropping the *it* subscripts for simplicity):

(3) $\dot{TFP} = TC + EC$

where $TC = \dfrac{\partial f(x,t;\beta)}{\partial t}$, a shift of the production frontier representing technical change, and

technical efficiency change, EC, is the rate at which a country moves toward or away from the

production frontier, which itself shifts through time as measured by TC.

The technical efficiency change component requires a little more explanation given that it

will also be the basis for information that will lead us to answer the second question, the

identification of institutional and political factors that underlie differential productivity growth

performance across countries in SSA. Technical inefficiency is captured in equation (1) by the non-negative random variable u. The ratio of observed output for the i-th country relative to its potential output when the individual country effects are zero, is used to define the technical efficiency of the i-th country in period t, $TE_{it} = \dfrac{Y_{it}}{\exp[f(x_{it}; \beta) + v]} = \exp(-u_{it})$. This measure of technical efficiency takes on values of zero to one, with a value of one indicating full technical efficiency. It represents the observed output of the i-th country at time t relative to the output produced by a fully efficient country using the same input vector. The change in TE between two periods is EC.

Given that the TE term indicates discrepancies in the productivity performance across countries, the frontier methodology lends itself to the inclusion of potential determinants of country heterogeneity which we refer to as 'efficiency changing variables'. We follow Battese and Coelli and specify a frontier model where the technical inefficiency effects are defined to be an explicit function of country-specific institutional and socio-political variables. The technical inefficiency effect u_{it} for the i-th country in the t-th period has a truncated iid $N(\eta_{it}, \sigma_u^2)$ distribution, where the mean is

(4) $\eta_{it} = h_{it}\delta$,

in which h_{it} is a $(1 \times p)$ vector of variables that influence the efficiency of the country, and δ is a $(p \times 1)$ vector of unknown parameters to be estimated.

For implementation, the production function in (1) is approximated with a specific functional form that imposes minimal *a priori* assumptions, a flexible form. Two algebraic approximations to the production function (1) have been used in the literature, Taylor series and Fourier series, with the first being more common than the last. Gallant (1981, 1982) argues convincingly for the superiority of the Fourier approximation in economic applications. This

approximation of the true function has been shown by El Badawi, Gallant, and Souza (1982) to

approximate both the function itself and its derivatives. Following Gallant we use the Fourier

flexible form, a semi-nonparametric form that combines a standard translog function with a non-

parametric Fourier series. This form has not been used before in primal space to approximate a

production function or in the context of a production frontier. Details on the construction of this

form, as well as other details not reported here, can be found in Fulginiti, *et al*.

Data

Panel data on output and conventional agricultural inputs (land, labor, fertilizer, tractors

and animals) for 41 SSA countries for 1961-1999, are available from the FAOSTAT website.

These data have been used in nearly every previous study of agricultural productivity in SSA

countries. Summary statistics for the data set and other details of the data set may be found at

Fulginiti, *et al.*

Agricultural output is expressed as the quantity of agricultural production in millions of

1989-1991 "international dollars". We refer to land, labor, livestock, machinery and fertilizer as

traditional inputs. Agricultural land is measured as the sum of arable land and permanent crops

in thousand hectares. Agricultural labor is measured as the number of persons who are

economically actively engaged in agriculture, in thousands. The livestock variable is a weighted

average of the number of animals on farms in thousands. The farm machinery variable is the

number of agricultural tractors. Fertilizer is quantity of fertilizer plant nutrient consumed (N

plus P_2O_5 plus K_2O), in metric tons.

Two types of efficiency changing variables are considered in this analysis, those that

allow for *qualitative* input differences and those that may capture differences in the *institutional*

and socio-political environment across countries. In addition a dummy variable is included for Ethiopia for years after the secession of Eritrea in 1992. As there is no data for Eritrea prior to this date, we merge the data for both countries for the period 1992-1999 and call it Ethiopia.

Data availability restricts us to three input quality measures: (a) Labor quality proxied by adult illiteracy rate taken from the World Development Indicators 2001; (b) land quality proxied by percentage of land irrigated; and (c) a dummy variable for drought equal to one for a year in which a drought was identified in the country either by the Keck and Dinar study or the African Development Indicators, 2002, zero otherwise.

The institutional variables are as follows. (a) Colonial heritage represented by three dummy variables for countries that were colonies of (or within the sphere of influence of) Great Britain, France, and Portugal (versus former Belgian colonies, Liberia and Ethiopia as the reference set), as determined from the Encyclopedia Britannica. (b) Independence, represented by the number of years since independence, as determined from the Central Intelligence Agency World Factbook. (c) Armed conflict, represented by three dummy variables to indicate minor conflict, intermediate conflict and war (contrasted with no conflict), using data from Gleditsch *et al*. (d) Political rights/civil liberties, represented by two dummy variables categorizing countries as free or partly free (contrasted with not free) from the Freedom House index of political rights and civil liberties. Because the Freedom House variables are available only for the years 1972-1999, this shorter time series of 1148 observations will be referred to as the "freedom data", as opposed to the 1599 observations "base data" of all other variables that are available for 1961-1999.

Estimation

We estimate the Fourier flexible functional form using both the base data for 41 countries, and the freedom data for the same countries. Denote with $i = 1, \ldots, 41$ the countries, and with j and $k = 1, \ldots, 5$ the inputs x_{ijt} and x_{ikt} at each time period $t = 1, \ldots, 39$. Imposing symmetry, the Fourier production frontier we estimate is:

$$(6) \quad \ln Y_{it} = u_0 + \sum_{j=1}^{5} b_j x_{ijt} + \frac{1}{2}\sum_{j=1}^{5} c_{jj} x_{jj}^2 + \sum_{j=1}^{5}\sum_{k>j}^{5} c_{jk} x_{ijt} x_{ikt} + b_t t + \frac{1}{2} b_{tt} t^2 + \sum_{j=1}^{5} b_{jt} x_{ijt} t$$

$$+ [m_t \cos(z_t) + n_t \sin(z_t)] + \sum_{j=1}^{5}\sum_{k>j}^{5} [m_{jk} \cos(z_{ijt} - z_{ikt}) + n_{jk} \sin(z_{ijt} - z_{ikt})]$$

$$+ \sum_{j=1}^{5}\sum_{k>j}^{5} [m_{jk1} \cos(z_{ijt} - z_{ikt} - z_t) + n_{jk1} \sin(z_{ijt} - z_{ikt} - z_t)]$$

$$+ \sum_{j=1}^{5}\sum_{k>j}^{5} [m_{jk2} \cos(z_{ijt} - z_{ikt} + z_t) + n_{jk2} \sin(z_{ijt} - z_{ikt} + z_t)]$$

$$- u_{it} + v_{it}$$

where Y is agricultural output; x's are logarithms of inputs (land, labor, livestock, machinery, and fertilizer); t is time from 1 to 39 (a proxy for technical change); z's are rescaled x's and t; k designates a "multi-index" vector of integers that creates a specific index of the z_i's; b, c, m, n are parameters to be estimated, u is the one-sided technical inefficiency term assumed truncated at zero and distributed iid $N(\eta, \sigma_U^2)$ that captures heterogeneity across countries and is the basis for differences in technical efficiency. In order to allow for measurement error and other random factors the Fourier frontier is augmented with a random error v, an iid $N(0, \sigma_v^2)$ that is independent of u. The technical inefficiency term is specified as the following function of efficiency-changing variables, estimated simultaneously with equation (6):

$$(7) \quad u_{it} = h_{it}\delta + \xi_{it}$$

with random variable ξ_{it} sharing the distributional characteristics of random variable u_{it}.

The simultaneous maximum-likelihood procedure of the FRONTIER 4.1 program
(Coelli, 1996a) was used to estimate the 88 parameters in equation (6), 60 of which are Fourier
terms, and the 13 parameters (15 using the freedom data) in equation (7). These estimates are the
benchmark used to perform the tests below and are referred to as the "full" model. Details of
parameter estimates and test statistics are available in Fulginiti, *et al*.

Three sets of specification tests were performed. In the first the likelihood ratio tests
indicate that technical change was not Hicks-neutral.[3] In the second the likelihood ratio tests
reject elimination of several subsets of efficiency changing variables, indicating that the full
frontier model with all the country-specific variables in the efficiency term is appropriate.[4] In
the third set of tests we used likelihood ratios to compare six functional forms nested within the
model of equation (6), in accordance with the principle of downward selection. The functional
forms, estimated using both data sets, were: a 68 parameter Fourier form with 40 Fourier terms; a
48 parameter Fourier form with 20 Fourier terms; a 30 parameter Fourier form with 2 Fourier
terms; a 28 parameter translog form, and a 7 parameter Cobb-Douglas form.[5] For all these tests,

---

[3] The likelihood-ratio test statistic with both the base and the freedom data for the null hypothesis of no technical change is calculated to be 356.92 and 287.84 respectively, exceeding the 1% critical value 76.15 with 49 degrees of freedom. The likelihood-ratio test statistic with both the base and the freedom data for the null hypothesis of Hicks-neutral technical change is calculated to be 330.2 and 233.68 respectively, exceeding the 1% critical value with 45 degrees of freedom.

[4] Three tests are performed with both the base and the freedom data. The first one tests the null of no technical inefficiency (or the appropriateness of the one-sided error specification), the second test the null hypothesis of no country specific factors influencing technical inefficiency by setting the parameter γ (a ratio of standard errors) and all parameters in equation (7) to zero, the third tests the null that the parameters for subgroups of the efficiency changing variables are zero. Likelihood ratios for the first test are: 441.24 and 303.92 with 15 degrees of freedom for the base and freedom data respectively, rejecting at 99% significance level. Likelihood ratios for the second test are: 374.32 and 303.92 with 13 degrees of freedom respectively, rejecting at 99% significance level. Likelihood ratios for the third tests also reject the null for all four subgroups at the 99% significance level for both models.

[5] The Cobb-Douglas model only includes the linear terms in inputs and time. The Translog model adds the second - order Taylor approximation terms to the Cobb-Douglas form. The first Fourier model includes the Translog model and the first order Fourier terms of the time trend, $\cos(z_t)$ and $\sin(z_t)$. Ten pairs of first order Fourier terms of input ratios, $\cos(z_{ijt} - z_{ikt})$ and $\sin(z_{ijt} - z_{ikt})$, are added to obtain the next Fourier flexible form. The next model adds the

equation (7) included all 12 efficiency-changing variables (14 with the freedom data.)

Likelihood ratio tests caused us to reject, in every case, the hypothesis of a lower order form

contrasted with the next higher order form. By this criterion, then, the Fourier series terms

constitute significant additions to the model. The results imply that the full 68-parameter Fourier

model of equations (6) and (7) produces estimates of the production function and its derivatives

(therefore of technical change) with the least amount of approximation error.

It is at this point that we introduced the second criterion for model evaluation,

consistency of the estimated function with the properties implied by production theory. We

calculate production elasticities for each of the models estimated above to evaluate monotonicity.

Of all the forms, the Cobb-Douglas was the only one with no violations of monotonicity

(positive production elasticities). Expanding the specification from the 7-parameter Cobb-

Douglas to the 28-parameter translog created violations at about 90% of data points; adding in

addition the first two Fourier terms increased this percentage slightly; and adding the higher-

order Fourier terms resulted in violations at 99-100% of the data points (details available at

Fulginiti, *et al*.)   A high percentage of such violations has been a common finding among panel

studies of this type, as well as Monte Carlo studies (Fleissig, *et al*.). For SSA agriculture, for

example, the studies by Chan-Kang, *et al*., and by Thirtle, *et al*., report 100 percent monotonicity

violations. Thus as we added trigonometric terms we added instability to the functional form by

capturing small fluctuations in the data, even though statisitical tests indicate that the higher-

order terms minimize specification bias. This problem of a bias-stability tradeoff in choosing the

---

Fourier terms of the form $\cos(z_{ijt} - z_{ikt} - z_t)$ and $\sin(z_{ijt} - z_{ikt} - z_t)$, an addition of 10 pairs. The full model of equation (6) adds the Fourier terms of the form $\cos(z_{ijt} - z_{ikt} + z_t)$ and $\sin(z_{ijt} - z_{ikt} + z_t)$, an addition of 10 pairs.

number of Fourier terms has been previously identified by Gallant (1981, 1982), Chalfant,

Mitchell and Onvural, Terrell and Dashti, Fleissig, Kastens and Terrell and others.

We do not know of any formal method of resolving this tradeoff, so we proceed in an *ad-hoc* manner and choose the simplest Fourier form considered, which allows us to more flexibly estimate the time path of technical change:

$$(8) \qquad \ln Y_{it} = u_0 + \sum_{j=1}^{5} b_j x_{ijt} + \frac{1}{2}\sum_{j=1}^{5} c_{jj} x_{jj}^2 + \sum_{j=1}^{5}\sum_{k>j}^{5} c_{jk} x_{ijt} x_{ikt} + b_t t + \frac{1}{2} b_{tt} t^2 + \sum_{j=1}^{5} b_{jt} x_{ijt} t$$

$$+ [m_t \cos(z_t) + n_t \sin(z_t)] - u_{it} + v_{it}$$

with inefficiency specified as in (7). The first derivative of (8) with respect to t allows us to evaluate the rate of technical change, TC:

$$(9) \qquad \text{TC}_{it} = b_t + b_{tt} t + \sum_{j=1}^{5} b_{jt} x_{ijt} t + [m_t \cos(z_t) - n_t \sin(z_t)]\lambda$$

where λ is a common scaling factor (see Fulginiti, *et al.*)

We simultaneously fit equations (7) and (8) with a total of 28 translog parameters, 2 Fourier terms that approximate technical change, and 13 inefficiency parameters with the base data (15 with the freedom data.) For the base data, twenty-one out of forty-three parameters are significantly different from zero at the 95% confidence level while twenty-five of forty-five are significant using the freedom data (details available at Fulginiti, *et al*.) These parameters are used in equation (9) to evaluate technical change at each data point.

It is not very informative to discuss the average rate of technical change for all countries and years, because grand averages "hide" information. We find it more informative to look at the evolution of the annual average TC for the base and freedom models, evaluated using equation (9.) From the evolution of average TC shown in Figure 1 there are two obvious conclusions. First, the Fourier terms have shaped technical change. Second, the rate of technical

change for the whole region was negative in the 60's and 70's and turned positive during the 80's

and 90's.

Another empirical result of interest is the nature of the efficiency change, as reflected in

the estimates of δ from equation (7). We can see in Table 1 that the effect of illiteracy is

insignificant, that irrigation decreases inefficiency and drought increases it. While Chan-Kang,

et al., found illiteracy significant, Thirtle, *et al.*, found it insignificant. The drought and

irrigation results support the findings in the studies by Block, Frisvold and Ingram, Thirtle *et al.*,

and Chan-Kang *et al*. With respect to the institutional variables, accounting for colonial history

seems to be important, as well as political rights and civil liberties. The coefficients associated

with a higher level of political rights and civil liberties indicate that the more these rights are

respected, the more efficient is the country's agriculture, a result consistent with Chan-Kang, *et

al.* The variables indicating years since independence and the presence of conflict are not

individually significant, though they are significant as a group.[6]

Agricultural Productivity Performance in SSA

Our objectives have been to obtain measures of SSA agricultural productivity covering

the most complete set of countries and years to date, and to explore the potential role of

institutional variables in understanding differences between the performances of individual

countries. The pooled frontier production function of the previous section provides the basis for

addressing these objectives. We find that the area achieved average annual productivity gains of

---

[6] Likelihood ratio tests of the base and freedom data are 12.2 and 145.8 respectively with 3 degrees of freedom, rejecting the null at the 99% and 90% confidence levels respectively

0.83%[7] over the four decades . (All cross-country averages reported here are weighted by current share of SSA agricultural output.) This is consistent with the 0.49% estimated by FAO for approximately the same period and countries. It is quite different from the -.086% estimated by Suhariyanto, *et al*., although the decade-by-decade time path found in that study is nonetheless quite similar to ours.

Average gains were positive for each decade except the 1970's, when average productivity declined at the rate of 0.3% per year (Figure 2, Table 2). We find no readily evident causes for the failure during the 1970's. Drought was not unusually prevalent during that decade (drought was very widespread during 1982-84, but does not appear to reduce productivity during those years.) Wars and civil disturbances do not appear to be more severe during those years, either. Since 1985, average productivity gains for SSA agriculture have been quite strong, averaging 1.90% per year, a level comparable to those in industrialized countries. The "recovery" first noted by Block for the years 1983-88 seems to have persisted, despite his pessimism about that possibility.

Colonial heritage

In Table 3 we report the four-decade productivity growth rates for the individual countries. We have grouped the countries according to their colonial heritage, and it is evident that there are very substantial differences between these groups. The four former Portuguese colonies had the poorest performance, averaging -0.26% per year, with Liberia (former U.S. protectorate) about the same at -0.25%, the three former Belgian colonies next poorest with -0.17% per year. The14 former French colonies came next with a positive average productivity

---

[7] When Nigeria and South Africa, representing 17 percent and 13 percent respectively of production and having a 1.6 percent TFP growth are purged from the set, weighted average TFP for the rest of the countries is 0.43 percent.

gain of 0.52%, Ethiopia with an average productivity gain of 0.76%, while the 18 former British colonies performed the best with an average 1.08% productivity gain per year.

Figure 3 charts these differences by colonial heritage groupings. It shows that trends, as well as levels, differ among the groups. The three Belgian colonies have done badly during the 90's because of armed conflicts, resulting in a marked downward trend in the rate of productivity change over the four decades. The UK group showed not only the highest average level of productivity gains, but one of the highest growth rates in TFP gains, as well. The four ex-Portuguese colonies have had the strongest upward trend since the disastrous 1970's, achieving gains approximately equal to the ex-French colonies during the 1990's.

We note that within the British group, Nigeria and South Africa not only posted the highest productivity gains, 1.64% per year for each, but they are also the largest countries, constituting an average of 17% and 13% of SSA agricultural output over this period, respectively. Thus they are significant contributors to the relatively high productivity rates for the UK group. But the remaining 16 British countries nonetheless averaged a positive 0.32% productivity gain per year, with only six[8] experiencing overall deterioration in productivity.

Years since independence

One issue related to the time of independence is the path of productivity growth after independence. The regression results in Table 1 indicated a slightly positive (but statistically insignificant) trend in technical efficiency after independence. To picture the path of productivity after independence, we plot in Figure 4 the average rate of productivity growth experienced by all countries in a given year since independence (average is in this case a simple

---

[8] These are Botswana, Gambia, Lesotho, Malawi, Somalia, and Uganda.

average across countries.)   The path is quite erratic, though inspection and the quadratic trend line offer some evidence that productivity tends to be stagnant or decreasing during the first 12 years of independence, tending to increase thereafter.

Political Rights and Civil Liberties

As previously mentioned, we have acquired two indexes of political freedom that Freedom House has published for these and other countries, but they became available only beginning in 1972. Each year Freedom House has rated each country as "not free", "partly free", or "free", based on a series of checklists relating to political rights and civil liberties. To obtain an econometric estimate of the effect of political freedom, we re-estimated the Fourier form with data for the 1973-1999 period, including one dummy variable for "partly free" and another for "free." The results of this regression were in all respects very similar to those obtained with the base data for 1962-1999. The correlation between country average TFP measures predicted by the two models was 0.77, and that between aggregated annual average TFP measures was 0.98.

The coefficient of the "Partly Free" dummy was –0.26, and that of the "Free" dummy variable was –0.39, both highly significant. The interpretation is straightforward – in a year in which a country was rated "Partly free", the country is predicted to be 26% more technically efficient than when not free. In a year in which it was rated "Free", it is predicted to be 39% more efficient. From these results and average levels of the variables by country, it is reasonable to infer that average differences in political freedom between former Portuguese and former UK colonies, for example, explain a difference in technical efficiency of about 10%, and a difference in productivity level of the same amount. As discussed in the previous section, however, it is change in freedom that would impact productivity gains or losses, so it appears that there is

ample opportunity for all of these countries to improve their agricultural efficiency and productivity by increasing political rights and civil liberties.

Our results indicating the effect of colonial heritage on agricultural productivity growth corroborate previous findings by Bertocchi and Canova (2002), Grier (1999), Landes (1998) and North, *et al*., (1998), all of which found former British colonies to achieve higher per capita GDP growth rates than former French or Portuguese colonies. The explanations they advance for these differences are that institutions such as property rights, political freedom, free markets, etc., do matter in determining the vigor of economic growth. In our study, it is clear that respect for political and civil rights and absence of conflict are two of the institutional characteristics that contribute to the differences between the colonial groups with regard to agricultural productivity performance.

Conclusions

In this study of agricultural productivity in 41 Sub-Saharan Africa countries, we have found that the region made some progress in the 1960's, suffered a regression in productivity during the 1970's, but after the mid-1980's recovered to achieve a reasonably robust rate of productivity improvement through the end of the century. The over-all average rate of productivity growth for the four decades was estimated at 0.8% per year. The general nature of these results is consistent with several other studies of agricultural productivity in parts of SSA published since 1995, which should not be too surprising since the basic data sources are virtually the same. However, our analytical approach was quite different from any other study, with a broader geographical scope, and this provides some confidence in the robustness of the

estimates. Robustness is particularly useful in the case of SSA agriculture because of the limitations in the quantity and quality of data needed for the purpose.

We estimated TFP gain or loss for each country in each year as the sum of predicted change in the production frontier in that vicinity plus predicted change in technical efficiency for that country and year. We used the Battese-Coelli approach to estimate the efficiency effects of institutional and other efficiency-changing variables, with the production frontier specified as Gallant's Fourier flexible form. We found, as have others, that the use of a fully-parameterized Fourier flexible form (60 Fourier parameters in our case) could be justified by goodness-of-fit criteria, but created violations of the required monotonicity property.   Balancing these two criteria subjectively, we chose a very abbreviated Fourier form with only sine and cosine Fourier expansions of the time trend, which allowed us to retain flexibility in estimating the time path of technical change over the four-decade period.

A primary objective of the study was to examine the relationship between growth in productivity and institutional factors, following a number of recent studies showing that GDP growth rates are strongly affected by those factors. We found that 19 ex-British colonies experienced the highest TFP growth rates of colonial groupings, with three ex-Belgian colonies and Liberia the worst performers (their TFP diminished over the period), and 14 ex-French and four ex-Portuguese colonies having intermediate performance levels. These differences were determined in significant measure by the estimated effects of wars and civil conflicts and differences in political and civil liberties as measured by Freedom House indexes. These results indicate that institutional factors are important determinants of agricultural productivity growth, as well as per capita GDP growth as established in other recent studies.

Figure 1. Technical change in SSA during 1961-1999.

Figure 2. Annual average TFP change in 41 SSA countries.

Figure 3. Decade Average TFP by Colonial Heritage Groups

Figure 4. Average annual TFP increase by Years Since Independence

Table 1. Parameter estimates for efficiency changing variables, equation (7).

Variables	estimates (base data)	t-ratio	estimates (freedom data)	t-ratio
Efficiency intercept	0.27	1.84	-0.28	-0.85
Input quality				
Irrigation	-0.22	-24.48	-0.23	-20.61
Drought	0.15	3.26	0.12	2.43
Illiteracy	0.0005	0.63	-0.0005	-0.42
Institutional environment				
Independence	-0.002	-1.39	-0.001	-0.86
UK	0.23	2.19	0.73	2.64
France	-0.22	-2.13	0.17	0.62
Portugal	0.75	6.29	1.25	4.78
Minor conflicts	-0.11	-1.3	0.04	0.39
Intermediate conflicts	-0.19	-1.96	-0.04	-0.34
War	-0.05	-0.73	0.13	1.49
Free	-	-	-0.39	-4.66
Partly free	-	-	-0.26	-4.14
Ethiopia	-0.99	-1.52	-2.75	-1.92

Table 2 Average annual TFP change in SSA agriculture, by decade	
Decade	Average TFP change -----% per year----
1960's	0.68
1970's	-0.32
1980's	1.29
1990's	1.62
1961-1999	0.83

Table 3. Average 1962-99 TFP gains by country			
Former Belgian colonies:		**Former British colonies:**	
Burundi	-0.99	Botswana	-0.06
Dem Rep of Congo (Zaire)	-0.12	Gambia	-1.56
Rwanda	-0.01	Ghana	0.34
average	*-0.17*	Kenya	0.68
Former French colonies		Lesotho	-0.75
Benin	0.78	Malawi	-0.06
Burkina Faso	0.58	Mauritius	0.27
Cameroon	0.87	Namibia	0.48
Central African	0.95	Nigeria	1.59
Chad	0.34	Sierra Leone	0.11
Congo	-0.76	Somalia	-0.64
Côte d'Ivoire	0.57	South Africa	1.64
Gabon	0.13	Sudan	0.66
Guinea	-0.41	Swaziland	1.11
Madagascar	0.04	Tanzania	0.75
Mali	0.51	Uganda	-0.36
Niger	-0.43	Zambia	0.82
Senegal	-0.11	Zimbabwe	0.35
Togo	-0.08	*average*	*1.08*
average	*0.52*		
Former Portuguese colonies:		**Former U.S. colony:**	
Angola		Liberia	-0.25
Cape Verde	0.60	**Independent:**	
Guinea-Bissau	-0.26	Ethiopia	0.76
Mozambique	-0.36		
average	*-0.26*	*Ave., all countries*	*0.83*
